Information Retrieval

CS 547/DS 547

Worcester Polytechnic Institute
Department of Computer Science
Instructor: Prof. Kyumin Lee

Upcoming Schedule

- March 1: Midterm Exam
- March 3: due date of HW3
- March 17: due date of project proposal
- March 21: due date of proposal presentation slides

Midterm

- The exam will be held at 6pm next Wednesday in class.
- The exam is closed book.
- You may prepare and use one standard 8.5" by 11" piece of paper with any notes you think appropriate or significant.
- You may use a calculator if it make you feel comfortable. But no other electronic devices are allowed (e.g., cell phone, tablet and computer).

In 2022

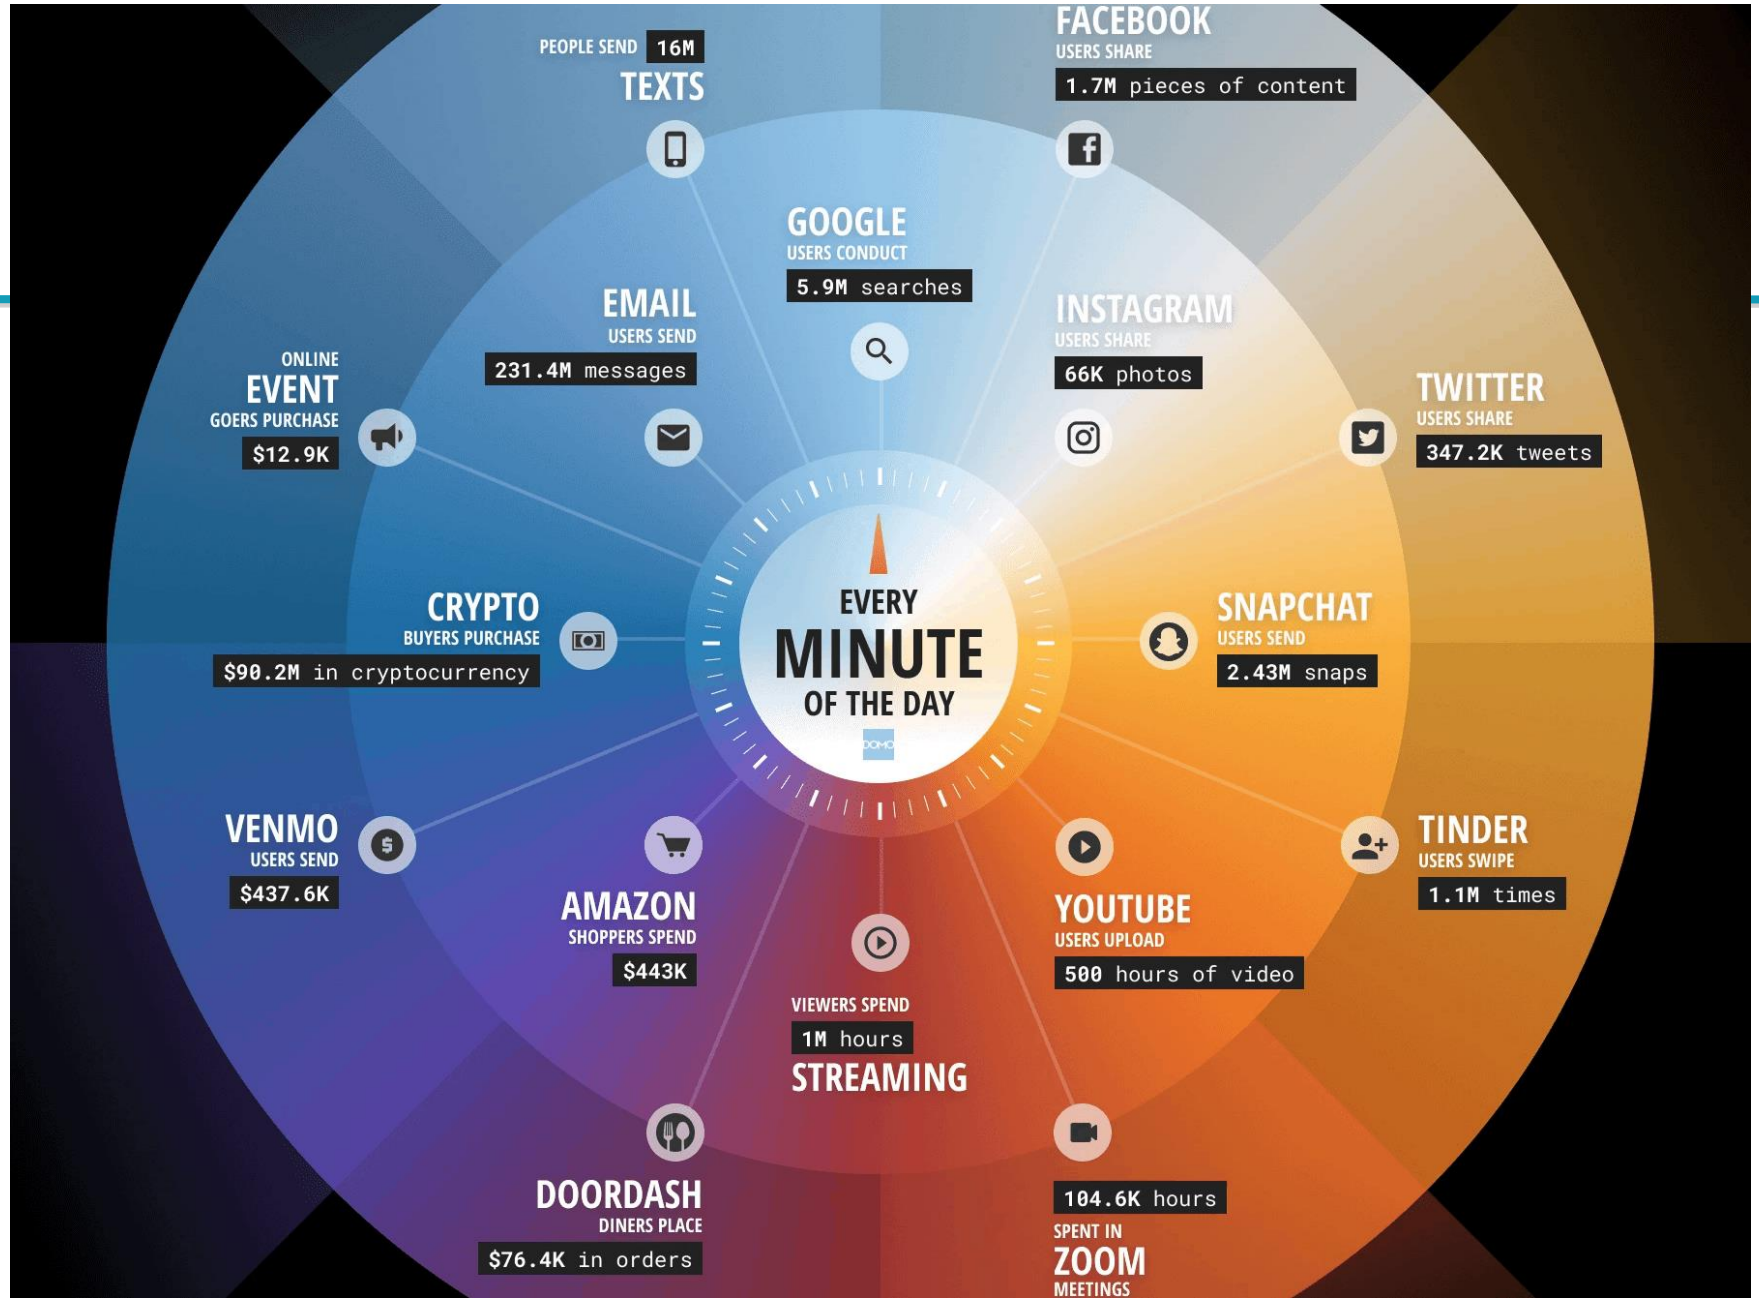

Image source: https://www.digitalinformationworld.com/2022/09/new-report-shares-mind-blowing-amount.html

How Many Products Does Amazon Sell?

Amazon itself sells over 12 million products. If you take into account all products sold on the Amazon marketplace by third-party sellers, that number rises to more than 353 million products.

How Many Orders Does Amazon Get A Day?

Amazon ships approximately **1.6 million packages a day**.

That works out to more than **66 thousand orders per hour**, and **18.5 orders per second**.

Amazon Sales Statistics: How Much Amazon Makes in a Day

In 2019, Amazon made $141.25 billion in retail product sales. This comes out to an average of $385 million **each day**.

https://landingcube.com/amazon-statistics/

About Spotify

Spotify transformed music listening forever when it launched in 2008. Discover, manage and share over 100 million tracks and 5 million podcasts titles, for free, or upgrade to Spotify Premium to access exclusive features for music including improved sound quality and an on-demand, offline, and ad-free music listening experience. Today, Spotify is the world's most popular audio streaming subscription service with 489 million users, including 205 million subscribers in more than 180 markets.

YouTube Usage Statistics

YouTube users consume 1 billion hours' worth of video every day. This figure translates to approximately 5 billion videos every day.

- The average time spent on YouTube by a user is 11.24 minutes.
- It is estimated that YouTube has around 5 billion videos.
- 500 hours of video is uploaded to YouTube every minute.

https://www.demandsage.com/youtube-stats/

Movies For You
Welcome!
The Netflix Prize seeks to substantially improve the accuracy of predictions about how much someone is going to love a movie based on their movie preferences. Improve it enough and you win one (or more) Prizes. Winning the Netflix Prize improves our ability to connect people to the movies they love.
Read the Rules to see what is required to win the Prizes. If you are interested in joining the quest, you should register a team.
You should also read the frequently-asked questions about the Prize. And check out how various teams are doing on the Leaderboard.
Good luck and thanks for helping!

Formal Model

- X = set of Customers (Users)
- S = set of Items

- Utility function u: $X \times S \rightarrow R$
  - R = set of ratings
  - R is a totally ordered set
  - e.g., 0-5 stars, real number in [0,1]

Utility Matrix

	The Lego Movie	The Fault in Our Stars	Guardians of the Galaxy	Star Wars
Alice	1		0.2	
Bob		0.5		0.3
Carol	0.2		1	
David				0.4

Key Problems

- Gathering “known” ratings for matrix
- Extrapolate unknown ratings from the known ones
  - Mainly interested in high unknown ratings
  - Don’t care about finding what you **don’t like**, but rather what you like
- Evaluating extrapolation methods
  - How do we know if we’ve done a good job?

Gathering Ratings

- Explicit
  - Ask people to rate items
  - Doesn't work well in practice – people can't be bothered
- Implicit
  - Learn ratings from user actions
    - E.g., purchase implies high rating, clicks, listen to a song
  - What about low ratings?
    - Called negative sampling
      - Random sampling, popularity-based sampling, and so on.

(2) Extrapolating Utilities

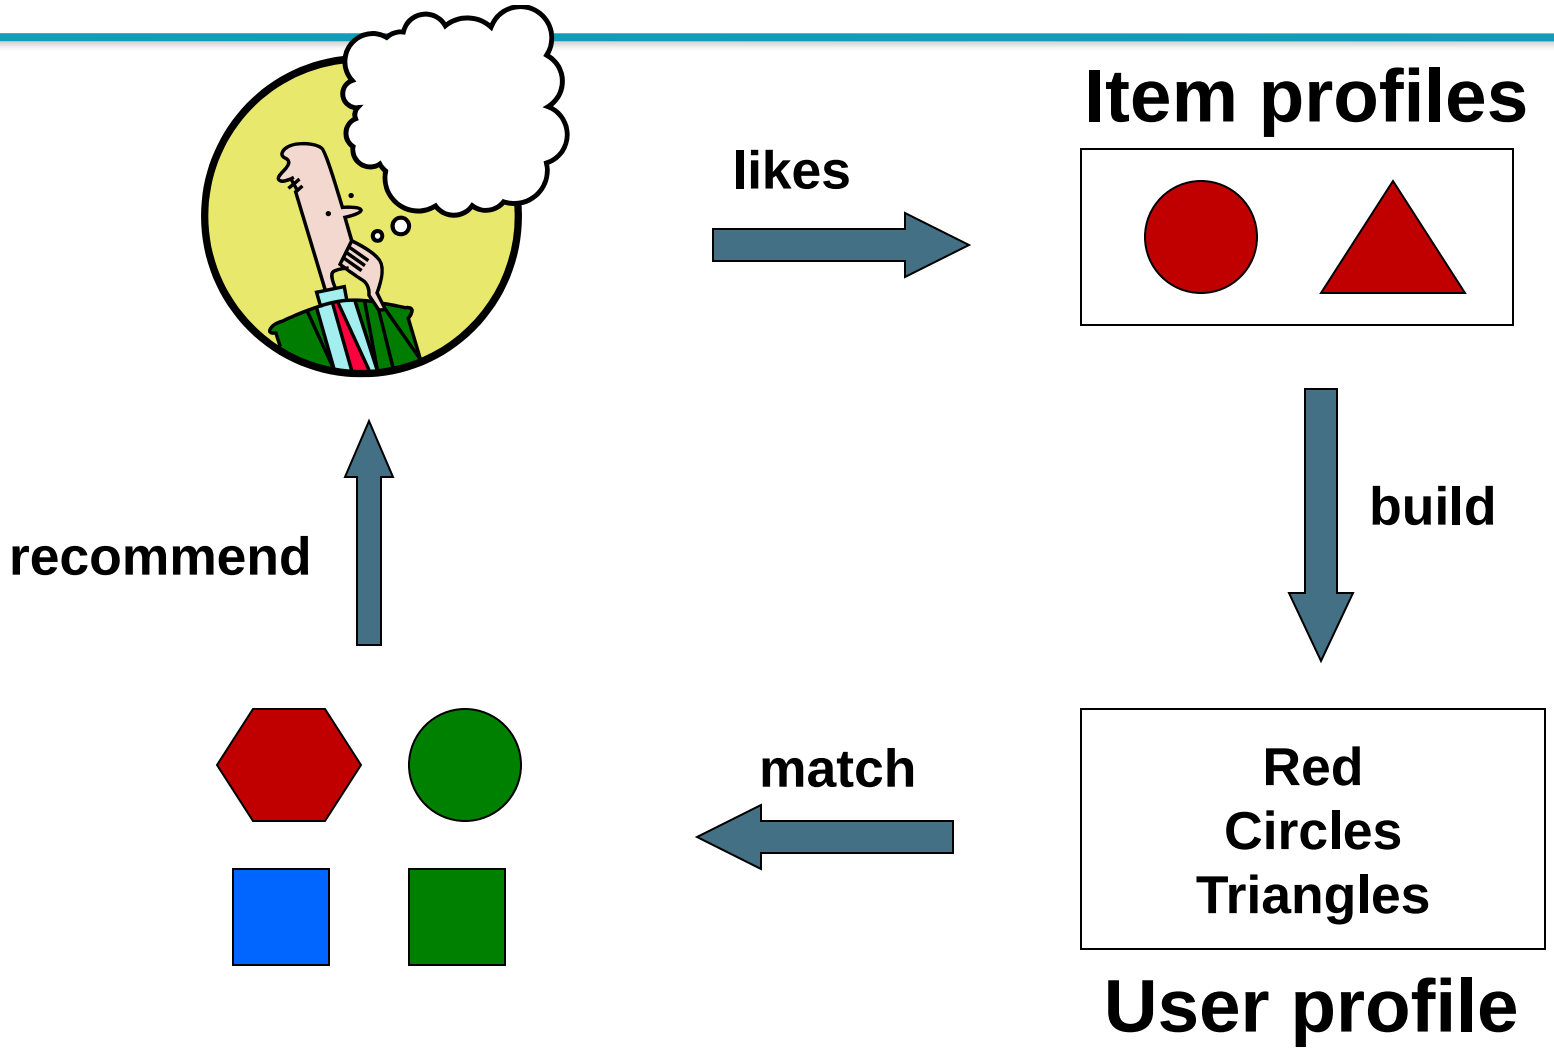
- Key problem: Utility matrix *U* is sparse
  - Most people have not rated most items
  - Cold start:
    - New items have no ratings
    - New users have no history
- Three main approaches
  - Content-based
  - Collaborative
  - Latent factor based
- These days, people focus on neural network/deep learning based approaches to capture more complex relation between users and items

Content-based Recommender Systems

Content-based Recommendations

- **Main idea**: recommend items to customer ***x*** similar to previous items rated highly by ***x***
- Movie recommendations
  - recommend movies with same actor(s), director, genre, …
- Websites, blogs, news
  - recommend other sites with “similar” content

Plan of Action



Item Profiles

- For each item, create an item profile
- Profile is a set of features (vectors!)
  - Movies: author, title, actor, director,…
  - Text: Set of “important” words in document
- How to pick important features?
  - Usual heuristic is TF-IDF

Sidenote: TF-IDF

f_{ij} = frequency of term (feature) *i* in doc (item) *j*

Note: we normalize TF to discount for "longer" documents

$$TF_{ij} = \frac{f_{ij}}{\max_k f_{ik}}$$

← Whichever doc/item has the max # of frequency of term i

n_i = number of docs that mention term *i*

N = total number of docs

$$IDF_i = \log \frac{N}{n_i}$$

TF-IDF score: $w_{ij} = TF_{ij} \times IDF_i$

Doc/item profile = set of words with highest TF-IDF scores, together with their scores

User Profiles and Prediction

- User profile possibilities:
  - Weighted average of rated item profiles
  - Variation: weight by difference from average rating for item
  - …
- Prediction heuristic
  - Given user profile **x** and item profile **i**, estimate
    - $u(\mathbf{x},\mathbf{i}) = \cos(\mathbf{x},\mathbf{i}) = \mathbf{x}.\mathbf{i}/(|\mathbf{x}||\mathbf{i}|)$

Advantages of Content-based Approach

- No need for data on other users
  - No cold-start or sparsity problems
- Able to recommend to users with unique tastes
- Able to recommend new & unpopular items
  - No first-rater problem
- Can provide explanations of recommended items by listing content-features that caused an item to be recommended

Limitations of content-based approach

- Finding the appropriate features is hard
  - e.g., images, movies, music
- Recommendations for new users
  - How to build a user profile?
- Overspecialization
  - Never recommends items outside user's content profile
  - People might have multiple interests
  - Unable to exploit quality judgments of other users

Collaborative Recommendations

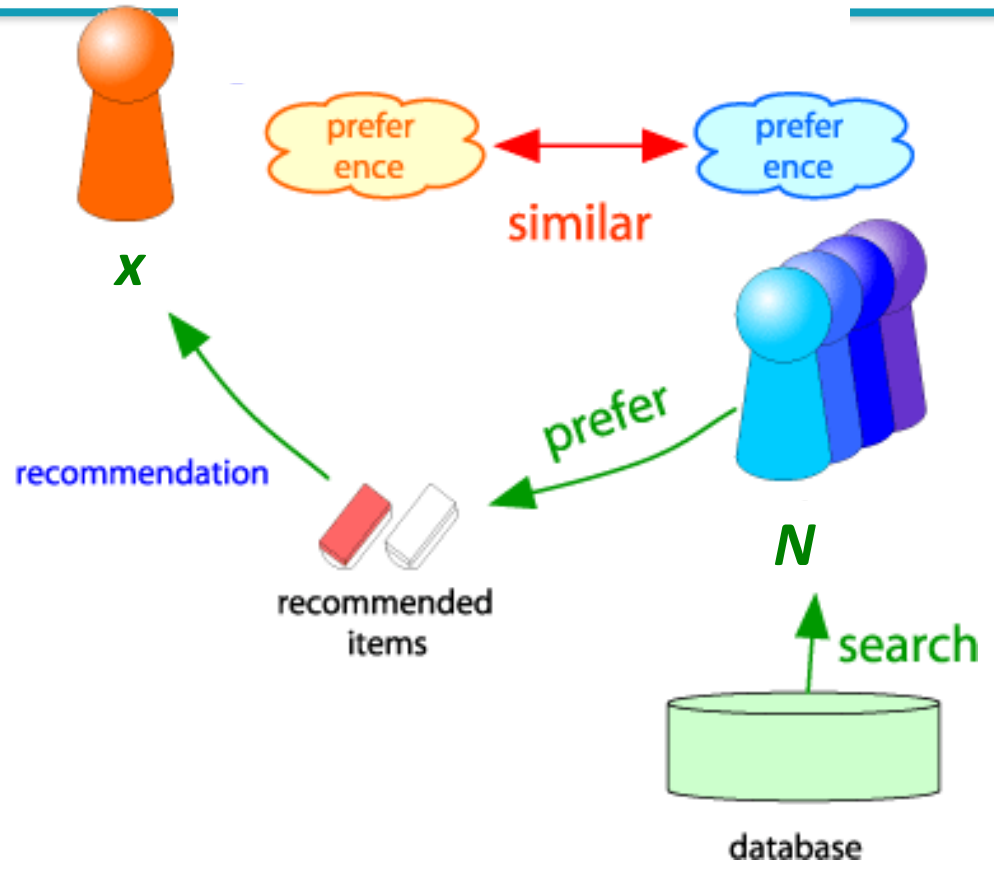
Collaborative Recommendations

- User-based recommendation

- Item-based recommendation

Collaborative Filtering

- Consider user ***x***
- Find set ***N*** of other users whose ratings are "**similar**" to ***x***'s ratings
- Estimate ***x***'s ratings based on ratings of users in ***N***



Finding "Similar" Users

r_x = [*, _, _, *, ***]
r_y = [*, _, **, **, _]

- Let r_x be the vector of user x's ratings
- **Jaccard similarity measure**
  - **Problem:** Ignores the value of the rating
- **Cosine similarity measure**
  - $\text{sim}(x, y) = \cos(r_x, r_y) = \frac{r_x \cdot r_y}{||r_x|| \cdot ||r_y||}$
  - **Problem:** Treats missing ratings as "negative"
- **Pearson correlation coefficient**
  - S_{xy} = items rated by both users x and y

$$sim(x,y) = \frac{\sum_{s \in S_{xy}} (r_{xs} - \overline{r_x})(r_{ys} - \overline{r_y})}{\sqrt{\sum_{s \in S_{xy}} (r_{xs} - \overline{r_x})^2} \sqrt{\sum_{s \in S_{xy}} (r_{ys} - \overline{r_y})^2}}$$

r_x, r_y as sets:
r_x = {1, 4, 5}
r_y = {1, 3, 4}

r_x, r_y as points:
r_x = {1, 0, 0, 1, 3}
r_y = {1, 0, 2, 2, 0}

$\overline{r}_x$, $\overline{r}_y$ … avg. rating of **x**, **y**

Similarity Metric

	HP1	HP2	HP3	TW	SW1	SW2	SW3
A	4			5	1		
B	5	5	4				
C				2	4	5	
D		3					3

- Intuitively we want: sim(A,B) > sim(A,C)
- Jaccard: 1/5 < 2/4
- Cosine: 0.380 > 0.322
  - Considers missing ratings as “negative”
  - Solution: subtract the (row) mean

	HP1	HP2	HP3	TW	SW1	SW2	SW3
A	4			5	1		
B	5	5	4				
C				2	4	5	
D		3					3

Solution: subtract the (row) mean

	HP1	HP2	HP3	TW	SW1	SW2	SW3
A	$2/3$			$5/3$	$-7/3$		
B	$1/3$	$1/3$	$-2/3$				
C				$-5/3$	$1/3$	$4/3$	
D		0					0

- sim(A,B) vs sim (A,C)
  - 0.092 > -0.559

Notice cosine sim. is pearson correlation when data is centered at 0

Rating Predictions

From similarity metric to recommendations:

- Let $\boldsymbol{r_x}$ be the vector of user $\boldsymbol{x}$'s ratings
- Let $\boldsymbol{N}$ be the set of $\boldsymbol{k}$ users most similar to $\boldsymbol{x}$ who have rated item $\boldsymbol{i}$
- **Prediction for item i of *user x*:**
  - $r_{xi} = \frac{1}{k} \sum_{y \in N} r_{yi}$
  - $r_{xi} = \frac{\sum_{y \in N} s_{xy} \cdot r_{yi}}{\sum_{y \in N} s_{xy}}$

Shorthand:

$s_{xy} = sim(x, y)$

User-User CF (|N|=2)

users

movies	1	2	3	4	5	6	7	8	9	10	11	12

3	2	4		1	2		3		4	3	5	
4		2	4		5			4			2	
5			4	3	4	2					2	5
6	1		3		3			2			4	

Neighbor selection:
Identify users similar to user **5**, and rated item **1**

- estimate rating of movie **1** by user **5**

User-User CF (|N|=2)

users

movies	1	2	3	4	**5**	6	7	8	9	10	11	12
1	1		3		?	5			5		4	
2			5	4			4			2	1	3
3	2	4		1	2		3		4	3	5	
4		2	4		5			4			2	
5			4	3	4	2					2	5
6	1		3		3			2			4	

Similarity: -0.45 **0.21** 1.0 -0.15 **0.47** -0.71

Neighbor selection:
Identify users similar to user **5**, and rated item **1**

User-based CF (|K|=2)

users

movies	1	2	3	4	**5**	6	7	8	9	10	11	12
1	1		3		?	5			5		4	
2			5	4			4			2	1	3
3	2	4		1	2		3		4	3	5	
4		2	4		5			4			2	
5			4	3	4	2					2	5
6	1		3		3			2			4	

Similarity:-0.45 0.21 1.0 -0.15 0.47 -0.71

Compute similarity weights:

$s_{5,3}$=0.21, $s_{5,9}$=0.47

Predict by taking weighted average:

$r_{1,5}$ = (0.21*3 + 0.47*5) / (0.21+0.47) = 4.4

$$r_{xi} = \frac{\sum_{j \in K(i;x)} s_{ij} \cdot r_{jx}}{\sum s_{ij}}$$

User-based CF (|K|=2)

users

movies	1	2	3	4	**5**	6	7	8	9	10	11	12
1	1		3		4.4	5			5		4	
2			5	4			4			2	1	3
3	2	4		1	2		3		4	3	5	
4		2	4		5			4			2	
5			4	3	4	2					2	5
6	1		3		3			2			4	

Similarity:-0.45 0.21 1.0 -0.15 0.47 -0.71

Compute similarity weights:

$s_{5,3}$=0.21, $s_{5,9}$=0.47

Predict by taking weighted average:

$r_{1,5}$ = (0.21*3 + 0.47*5) / (0.21+0.47) = 4.4

$$r_{xi} = \frac{\sum_{j \in K(i;x)} s_{ij} \cdot r_{jx}}{\sum s_{ij}}$$

Issue with the user-based CF

- So far: user-based collaborative filtering

- Another view is **item-based CF**.

Item-based CF

- The item-based approach works by comparing items based on their pattern of ratings across users. The similarity of items *i* and *j* is computed as follows:

$$sim(i,j) = \frac{\sum_{\mathbf{u} \in U} (r_{\mathbf{u},i} - \bar{r}_{\mathbf{u}})(r_{\mathbf{u},j} - \bar{r}_{\mathbf{u}})}{\sqrt{\sum_{\mathbf{u} \in U} (r_{\mathbf{u},i} - \bar{r}_{\mathbf{u}})^2} \sqrt{\sum_{\mathbf{u} \in U} (r_{\mathbf{u},j} - \bar{r}_{\mathbf{u}})^2}}$$

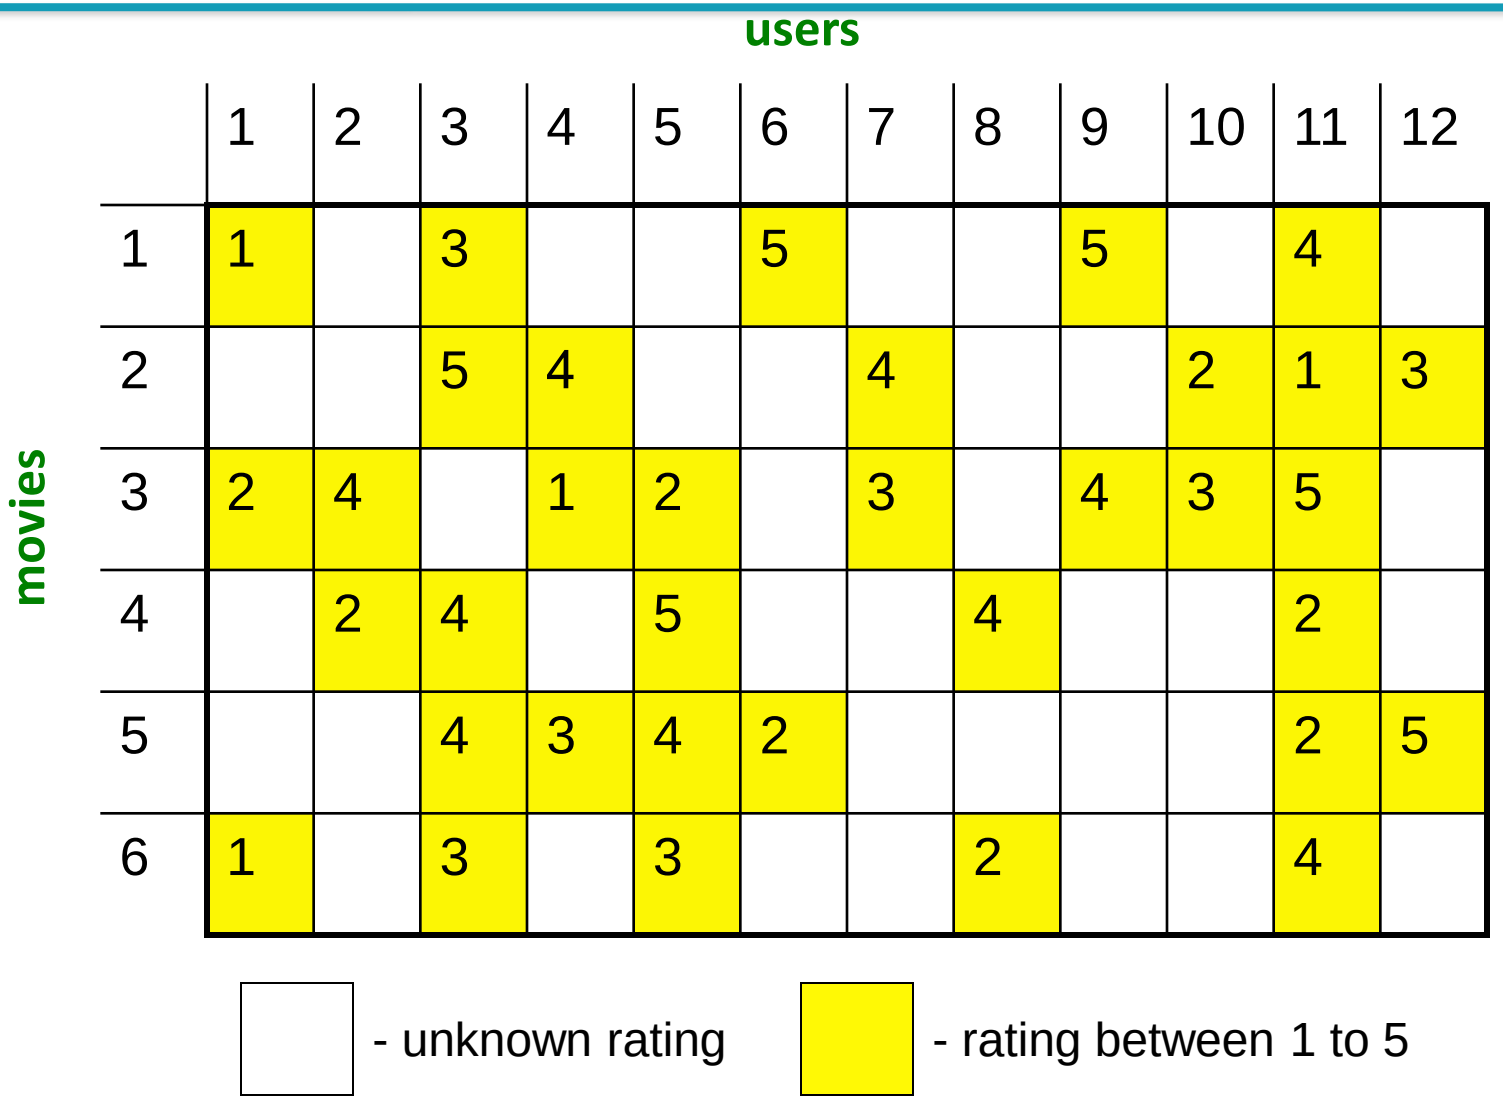
Recommendation phase

- After computing the similarity between items we select a set of *k* most similar items to the target item and generate a predicted value of user x's rating

$$r_{xi} = \frac{\sum_{j \in N(i;x)} s_{ij} \cdot r_{xj}}{\sum_{j \in N(i;x)} s_{ij}}$$

s_{ij}… similarity of items ***i*** and ***j***
r_{xj}…rating of user ***x*** on item ***j***
N(i;x)… set items rated by ***x*** similar to ***i***

Item-Item CF (|N|=2)



Item-Item CF (|N|=2)

users

movies

	1	2	3	4	**5**	6	7	8	9	10	11	12
1	1		3		?	5			5		4	
2			5	4			4			2	1	3
3	2	4		1	2		3		4	3	5	
4		2	4		5			4			2	
5			4	3	4	2					2	5
6	1		3		3			2			4	

- estimate rating of movie **1** by user **5**

Item-Item CF (|N|=2)

users

movies	1	2	3	4	**5**	6	7	8	9	10	11	12	sim(1,m)
1	1		3		?	5			5		4		**1.00**
2			5	4			4			2	1	3	**-0.18**
3	2	4		1	2		3		4	3	5		**0.41**
4		2	4		5			4			2		**-0.10**
5			4	3	4	2					2	5	**-0.31**
6	1		3		3			2			4		**0.59**

Neighbor selection:
Identify movies similar to movie **1**, **rated by user 5**

Here we use Pearson correlation as similarity:

1) Subtract mean rating m_i from each movie *i*

$m_1 = (1+3+5+5+4)/5 = 3.6$

row 1: *[-2.6, 0, -0.6, 0, 0, 1.4, 0, 0, 1.4, 0, 0.4, 0]*

2) Compute cosine similarities between rows

Item-Item CF (|N|=2)

users

movies	1	2	3	4	5	6	7	8	9	10	11	12	sim(1,m)
1	1		3		?	5			5		4		1.00
2			5	4			4			2	1	3	-0.18
3	2	4		1	2		3		4	3	5		**0.41**
4		2	4		5			4			2		-0.10
5			4	3	4	2					2	5	-0.31
6	1		3		3			2			4		**0.59**

Compute similarity weights:

$s_{1,3}$=0.41, $s_{1,6}$=0.59

Item-Item CF (|N|=2)

users

movies

	1	2	3	4	5	6	7	8	9	10	11	12	sim(1,m)
1	1		3		2.6	5			5		4		1.00
2			5	4			4			2	1	3	-0.18
3	2	4		1	2		3		4	3	5		0.41
4		2	4		5			4			2		-0.10
5			4	3	4	2					2	5	-0.31
6	1		3		3			2			4		0.59

Predict by taking weighted average:

$r_{1.5}$ = (0.41*2 + 0.59*3) / (0.41+0.59) = 2.6

$$r_{xi} = \frac{\sum_{j \in N(i;x)} s_{ij} \cdot r_{jx}}{\sum s_{ij}}$$

Item-Item vs. User-User

	Avatar	LOTR	Matrix	Pirates
Alice	1		0.8	
Bob		0.5		0.3
Carol	0.9		1	0.8
David			1	0.4

- **In practice, it has been observed that item-item often works better than user-user**
- **Why?** Items are simpler, users have multiple tastes

Pros/cons of collaborative filtering

- Works for any kind of item
  - No feature selection needed
- Cold start:
  - Need enough users in the system to find a match
- Sparsity:
  - The user/ratings matrix is sparse
  - Hard to find users that have rated the same items
- First rater:
  - Cannot recommend an item that has not been previously rated
  - New items, esoteric items
- Popularity bias:
  - Cannot recommend items to someone with unique taste
  - Tends to recommend popular items

Hybrid Methods

Hybrid Methods

- Add content-based methods to collaborative filtering
  - item profiles for new item problem
  - demographics to deal with new user problem
- Implement two separate recommenders and combine predictions
  - Perhaps using a linear model
  - E.g., global baseline + collaborative filtering

Global baseline estimate

- **Estimate Joe's rating for the movie The Sixth Sense**
  - No feature selection needed
  - Problem: Joe has not rated any movie similar to The Sixth Sense

- **Global baseline estimate**
  - Mean movie rating: **3.7 stars**
  - The Six Sense is **0.5 stars** above avg
  - Joe rates **0.2 stars** below avg
  - Baseline estimate: **3.7 + 0.5 – 0.2 = 4 stars**

Combining Global Baseline with CF

- **Global Baseline estimate:**
  - *Joe* will give *The Sixth Sense* 4 stars
- **Local neighborhood (CF/NN):**
  - *Joe* didn't like related movie *Signs*
  - Rated it 1 star below his average rating
- **Final estimate**
  - *Joe* will rate *The Sixth Sense* 4 – 1 = 3 stars

CF: Common practice

Before:

$$r_{xi} = \frac{\sum_{j \in N(i;x)} s_{ij} r_{xj}}{\sum_{j \in N(i;x)} s_{ij}}$$

- Define **similarity s_{ij}** of items ***i*** and ***j***
- Select ***k*** nearest neighbors ***N(i; x)***
  - Items most similar to ***i***, that were rated by ***x***
- Estimate rating r_{xi} as the weighted average:

$$r_{xi} = b_{xi} + \frac{\sum_{j \in N(i;x)} s_{ij} \cdot (r_{xj} - b_{xj})}{\sum_{j \in N(i;x)} s_{ij}}$$

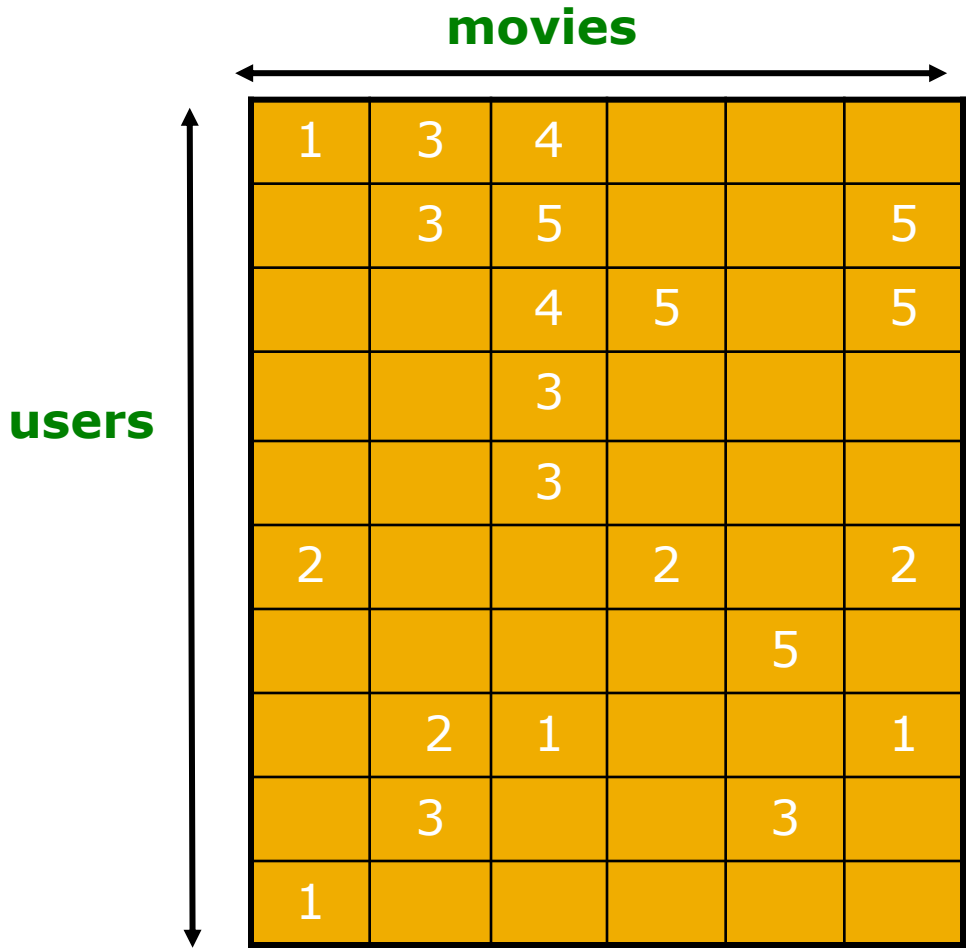
baseline estimate for r_{xi}

$$b_{xi} = \mu + b_x + b_i$$

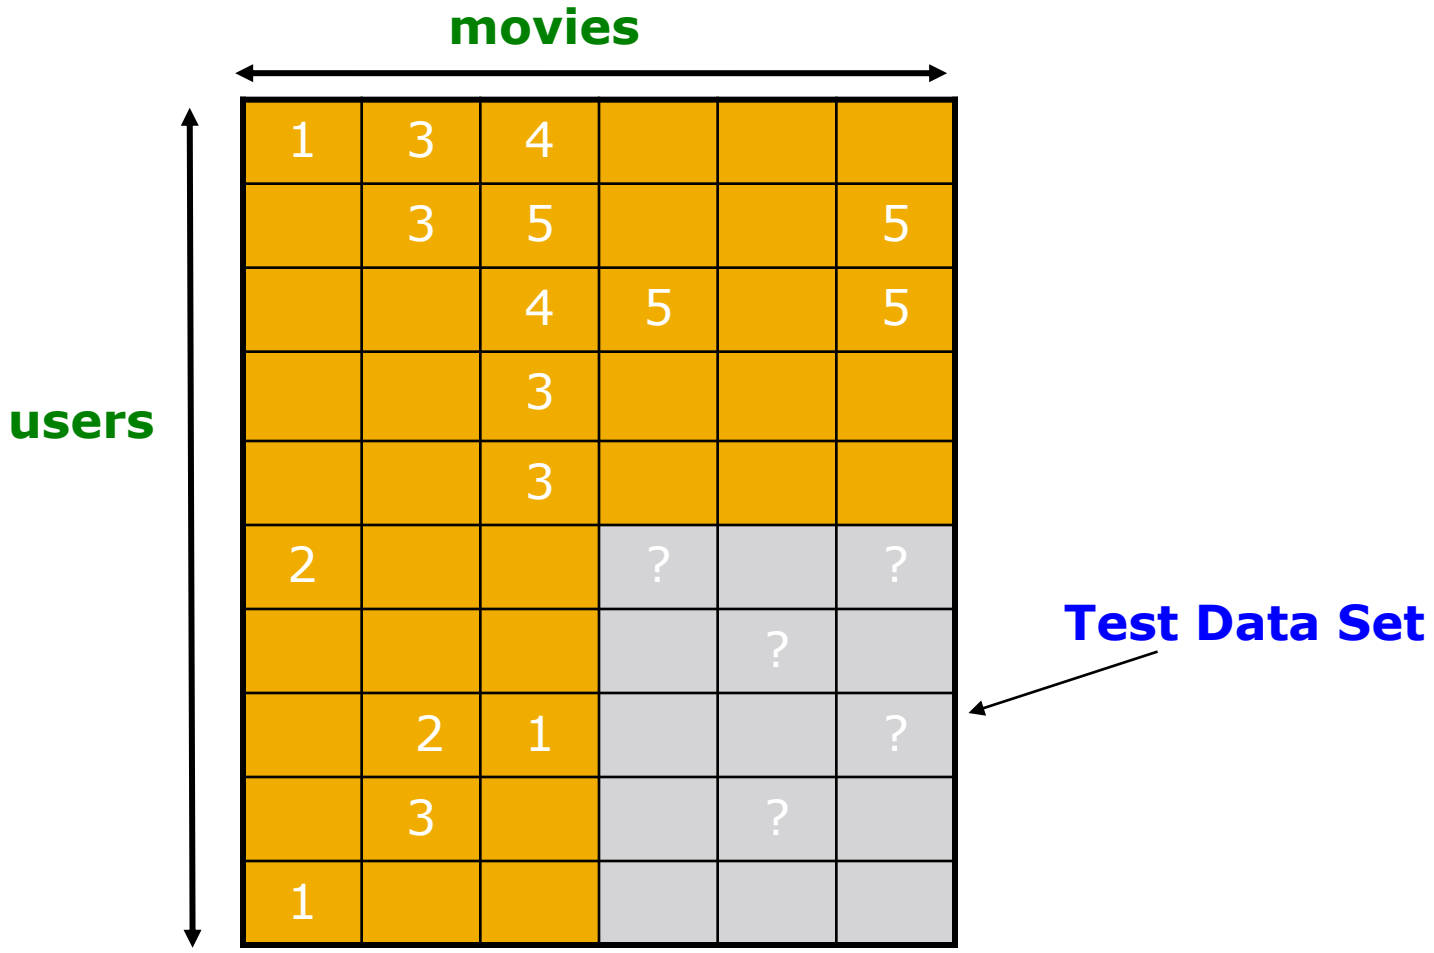
- μ = overall mean movie rating
- b_x = rating deviation of user ***x***
  = (*avg. rating of user **x***) – μ
- b_i = rating deviation of movie ***i***

Evaluation

Evaluation



Evaluation



Evaluation Predictions

- **Root-mean-square error** (RMSE)

  $\sqrt{\frac{1}{|R|}\sum_{(i,x)\in R}(\hat{r}_{xi} - r_{xi})^2}$ where $\hat{r}_{xi}$ is predicted, r_{xi} is the true rating of ***x*** on ***i***

- **Problems with Error Measures**
  - **Narrowly focus on accuracy sometimes misses the point**
    - Order of predictions
- **In practice, we care only to predict high ratings:**
  - RMSE might penalize a method that does well for high ratings and badly for others
- **Alternative: Precision@*k*, Hit Rate@*k* *(i.e., recall of positive interactions)*, and NDCG@*k***
  - ***E.g., k=10***

Three ways running Jupyter Notebook

- 1. Install Jupyter Notebook
  - https://jupyter.org/install
- 2. install Anaconda (if you installed it before, Jupyter Notebook was already installed together)
  - https://www.anaconda.com/products/individual
  - Beyond all of the normal (non-data centric) packages that Python comes with, Anacoda comes with even more!
- 3. Use a cloud computing (e.g., Google Colab)
  - https://colab.research.google.com/notebooks/intro.ipynb#recent=true

Google Colab

- **Google** Colaboratory is a free online cloud-based **Jupyter notebook** environment that allows us to train our machine learning and deep learning models on CPUs, GPUs, and TPUs.

https://www.youtube.com/watch?v=inN8seMm7UI

Recommendation Demo

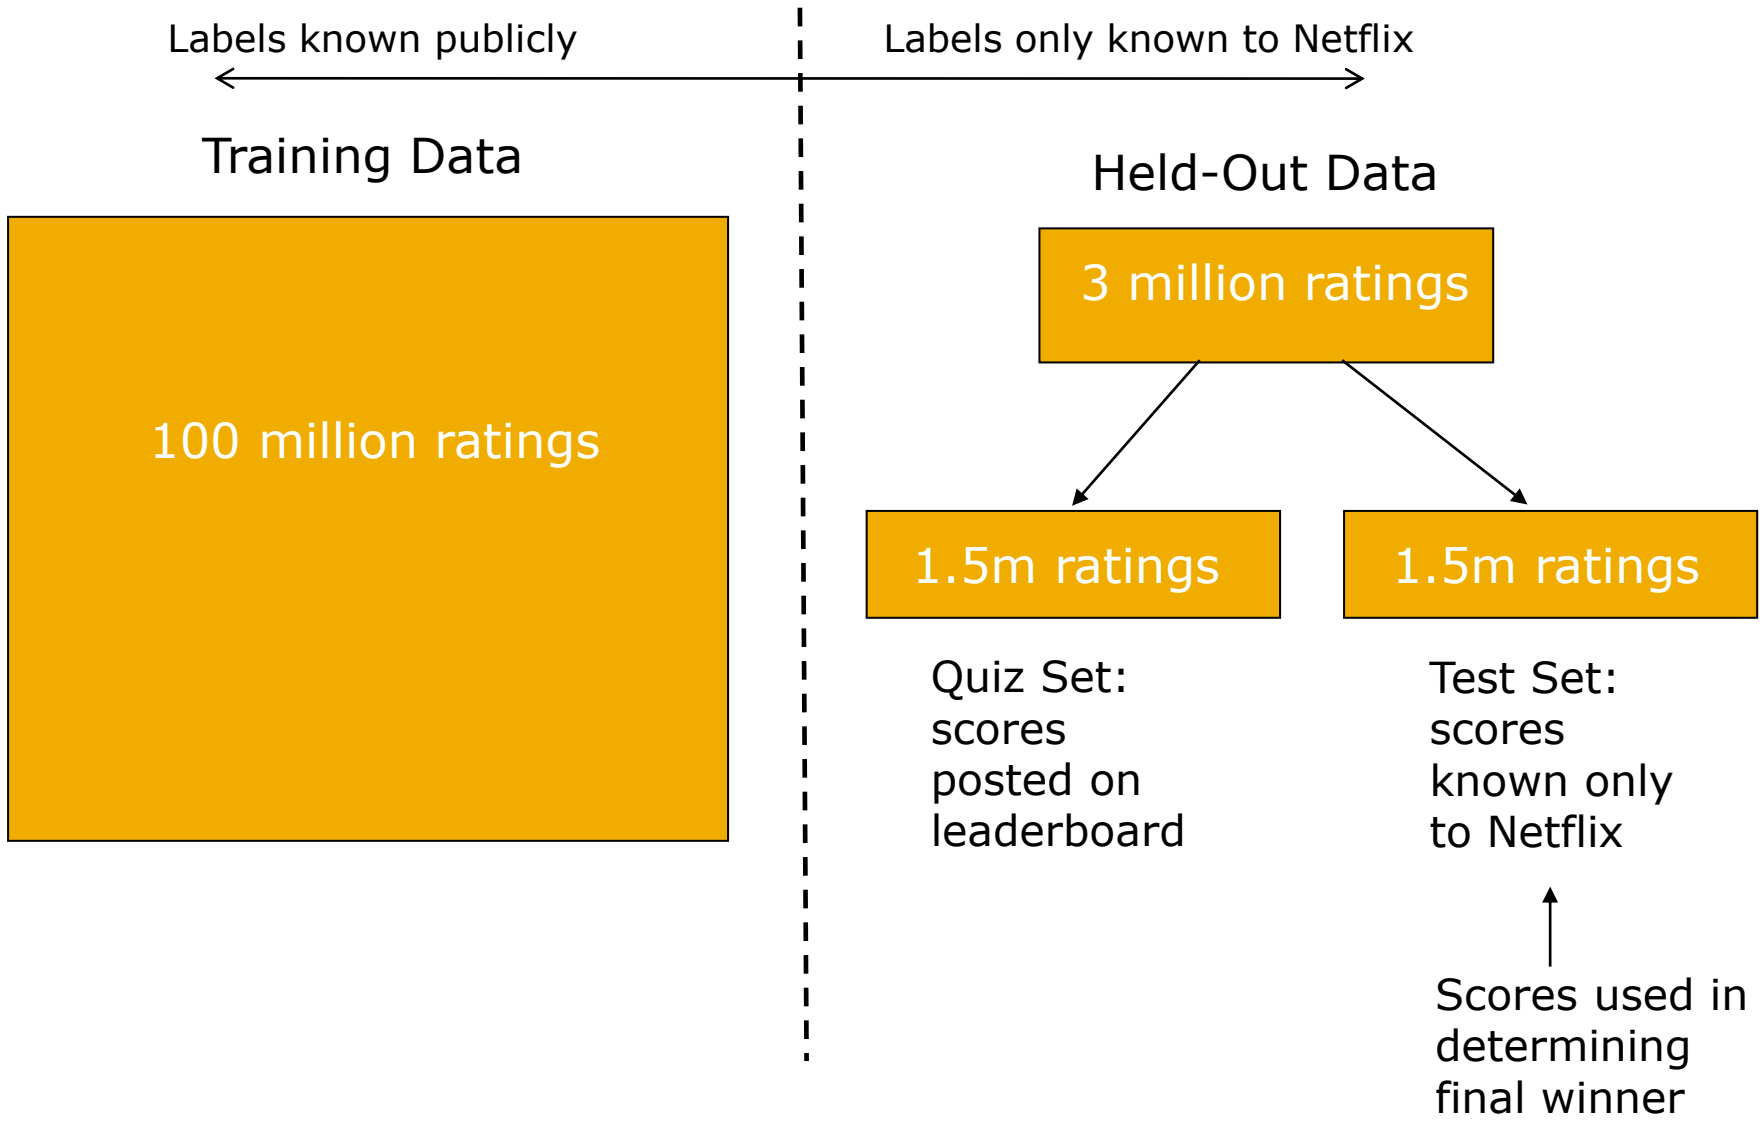
- recommenderDemo.ipynb

Latent Factor Models

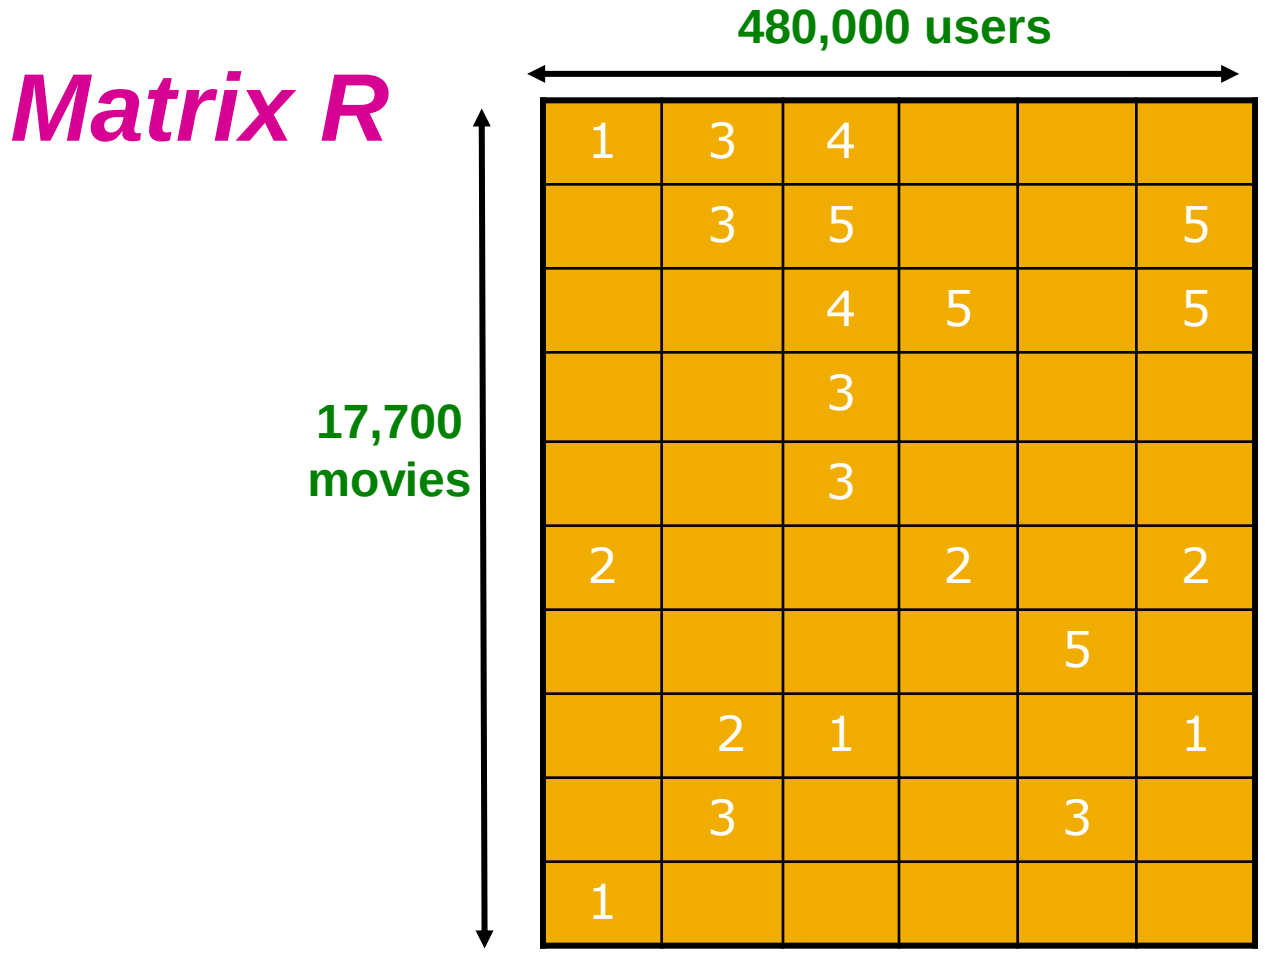
The Netflix Prize

- **Training data**
  - 100 million ratings, 480,000 users, 17,770 movies
  - 6 years of data: 2000-2005
- **Test data**
  - Last few ratings of each user (2.8 million)
  - **Evaluation criterion:** Root Mean Square Error (RMSE) $=$ $\sqrt{\frac{1}{|R|}\sum_{(i,x)\in R}(\hat{r}_{xi} - r_{xi})^2}$
  - **Netflix's system RMSE: 0.9514**
- **Competition**
  - 2,700+ teams
  - **$1 million** prize for 10% improvement on Netflix

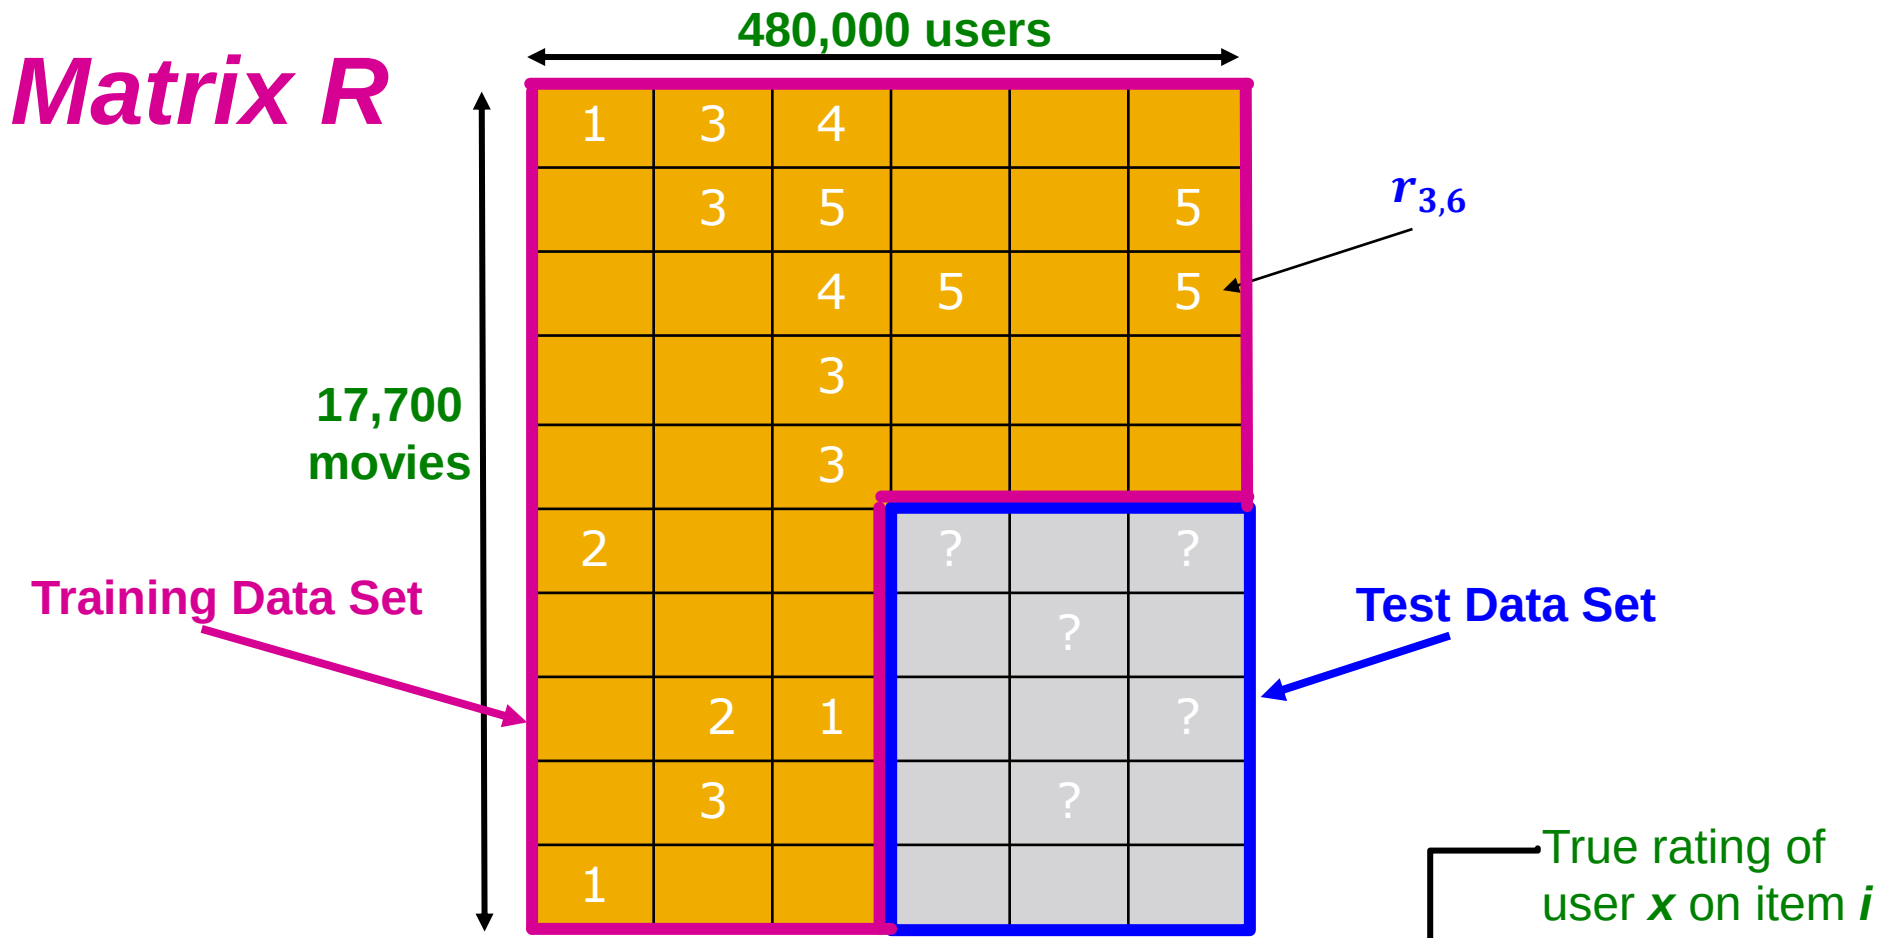
Competition Structure



The Netflix Utility Matrix *R*



Utility Matrix *R*: Evaluation

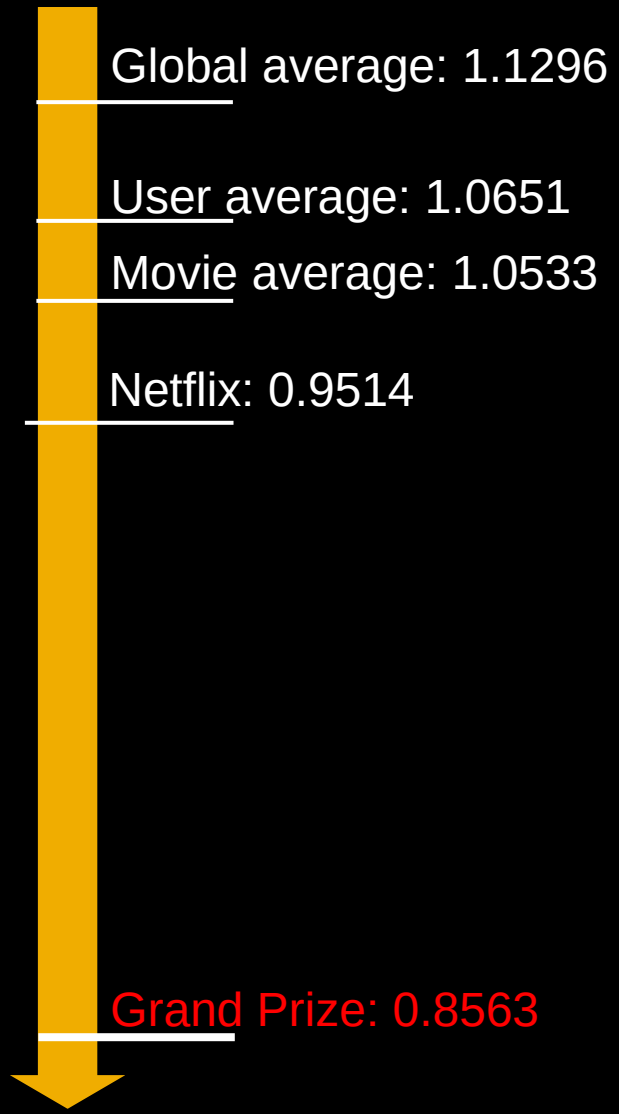


$$\text{RMSE} = \sqrt{\frac{1}{|R|}\sum_{(i,x)\in R}(\hat{r}_{xi} - r_{xi})^2}$$

True rating of user ***x*** on item ***i***

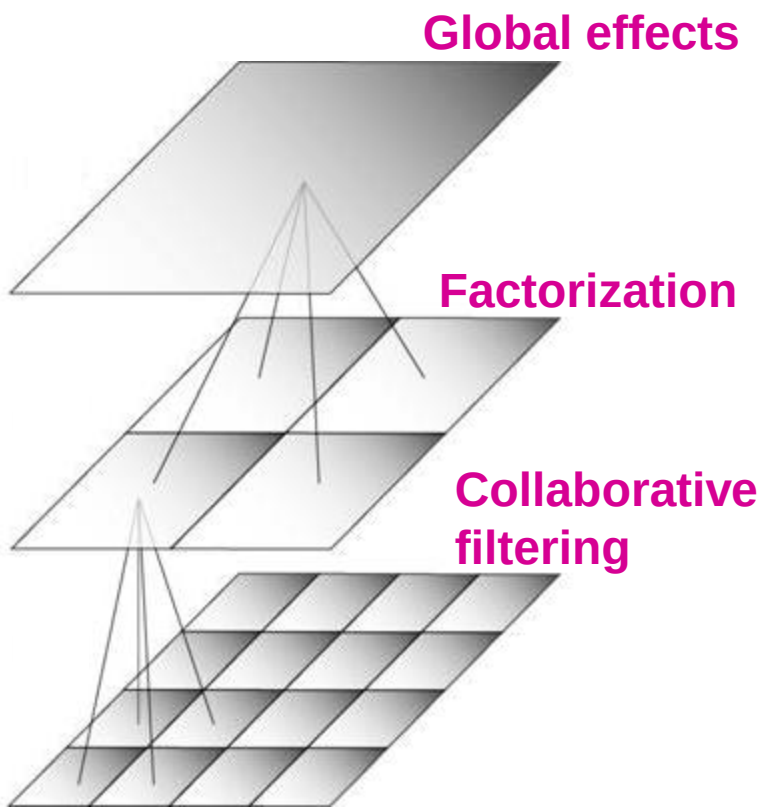
Predicted rating

Performance of Various Methods



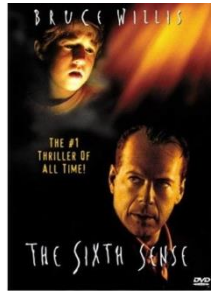
BellKor Recommender System

- **The winner of the Netflix Challenge**
- **Multi-scale modeling of the data:**
  Combine top level, "regional" modeling of the data, with a refined, local view:
  - **Global:**
    - Overall deviations of users/movies
  - **Factorization:**
    - Addressing "regional" effects
  - **Collaborative filtering:**
    - Extract local patterns



Modeling Local & Global Effects

- **Global:**
  - Mean movie rating: **3.7 stars**
  - *The Sixth Sense* is **0.5** stars above avg.
  - Joe rates **0.2** stars below avg.
    ⇒ **Baseline estimation:**
    ***Joe* will rate *The Sixth Sense* 4 stars**



- **Local neighborhood (CF/NN):**
  - *Joe* didn't like related movie *Signs*
  - Rated it 1 star below his average rating

- **Final estimate**
  - *Joe* will rate *The Sixth Sense* 4 – 1 = 3 stars

Modeling Local & Global Effects

- **In practice we get better estimates if we model deviations:**

$$\hat{r}_{xi} = b_{xi} + \frac{\sum_{j \in N(i;x)} s_{ij} \cdot (r_{xj} - b_{xj})}{\sum_{j \in N(i;x)} s_{ij}}$$

baseline estimate for r_{xi}

$$b_{xi} = \mu + b_x + b_i$$

μ = overall mean rating
b_x = rating deviation of user x
= (*avg. rating of* user x) $- \mu$
b_i = (*avg. rating of* movie i) $- \mu$

Problems/Issues:

1) Similarity measures are "arbitrary"

2) Pairwise similarities neglect interdependencies among users

3) Taking a weighted average can be restricting

Solution: **Instead of s_{ij} use w_{ij} that we estimate directly from data**

Idea: Interpolation Weights w_{ij}

- Use a **weighted sum** rather than **weighted avg.**:

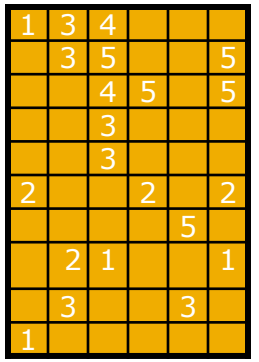
$$\widehat{r_{xi}} = b_{xi} + \sum_{j \in N(i;x)} w_{ij}\left(r_{xj} - b_{xj}\right)$$

- **A few notes:**
  - $\boldsymbol{N(i; x)}$ … set of movies rated by user ***x*** that are similar to movie ***i***
  - $\boldsymbol{w_{ij}}$ is the **interpolation weight** (some real number)
    - Note, we allow: $\boldsymbol{\sum_{j \in N(i;x)} w_{ij} \neq 1}$
  - $\boldsymbol{w_{ij}}$ models interaction between pairs of movies (it does not depend on user ***x***)

Idea: Interpolation Weights w_{ij}

- $\widehat{r_{xi}} = b_{xi} + \sum_{j \in N(i,x)} w_{ij}\left(r_{xj} - b_{xj}\right)$
- **How to set w_{ij}?**
  - Remember, error metric is: $\sqrt{\frac{1}{|R|}\sum_{(i,x)\in R}(\hat{r}_{xi} - r_{xi})^2}$ or equivalently Sum of Squared Error (**SSE**): $\sum_{(i,x)\in R}(\hat{r}_{xi} - r_{xi})^2$
  - Find w_{ij} that minimize **SSE** on **training data!**
    - Models relationships between item ***i*** and its neighbors ***j***
  - w_{ij} can be **learned/estimated** based on ***x*** and all other users that rated ***i***

Recommendations via Optimization



- **Goal:** Make good recommendations
  - Quantify goodness using **RMSE:**
    Lower RMSE ⇒ better recommendations
  - Want to make good recommendations on items that user has not yet seen. Can't really do this!
  - **Let's build a system such that it works well on known (user, item) ratings**
    And **hope** the system will also predict well the **unknown ratings**

Recommendations via Optimization

- **Idea:** Let's set values *w* such that they work well on known (user, item) ratings
- **How to find such values *w*?**
- **Idea:** Define an objective function and solve the optimization problem

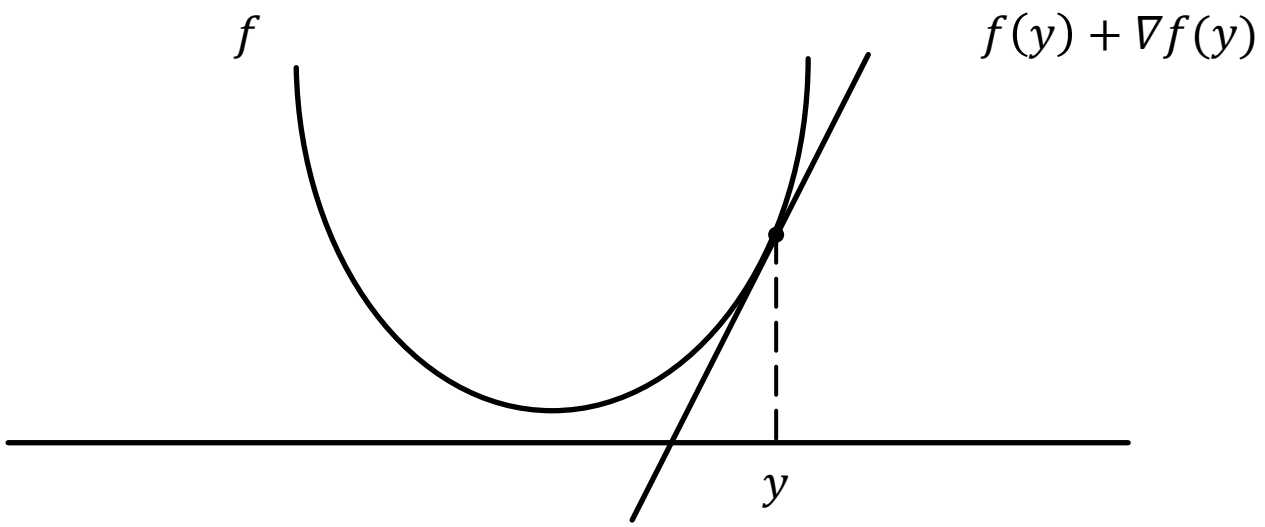
- Find w_{ij} that minimize **SSE** on **training data**!

$$J(w) = \sum_{x,i \in R} \left(\underbrace{\left[b_{xi} + \sum_{j \in N(i;x)} w_{ij}\left(r_{xj} - b_{xj}\right) \right]}_{\text{Predicted rating}} - \underbrace{r_{xi}}_{\text{True rating}} \right)^2$$

- Think of $\boldsymbol{w}$ as a vector of numbers

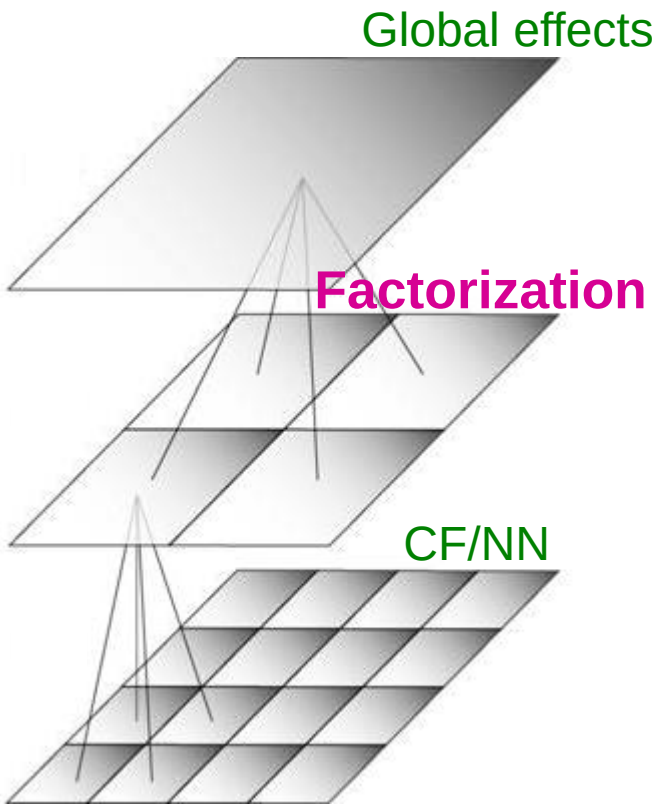
Detour: Minimizing a function

- **A simple way to minimize a function $f(x)$:**
  - Compute the derivative $\nabla f(x)$
  - **Start at some point y and evaluate $\nabla f(y)$**
  - **Make a step in the reverse direction of the gradient: $y = y - \nabla f(y)$**
  - **Repeat until converged**

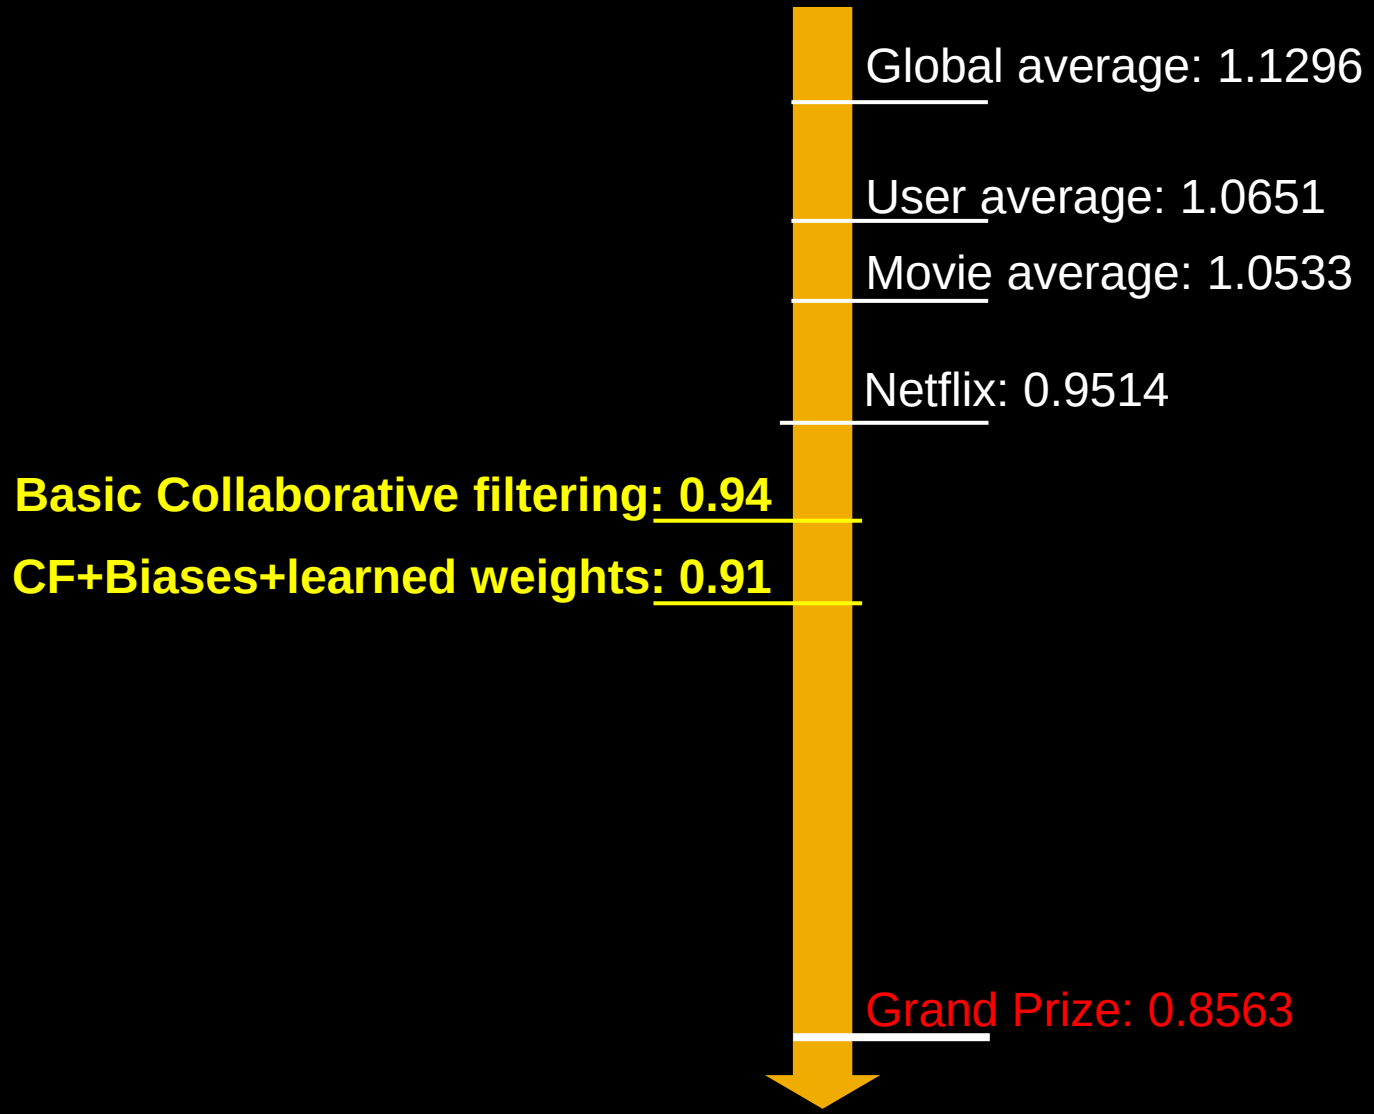


Interpolation Weights

- **So far:** $\widehat{r_{xi}} = b_{xi} + \sum_{j \in N(i;x)} w_{ij}\left(r_{xj} - b_{xj}\right)$
  - Weights $\boldsymbol{w_{ij}}$ derived based on their role; **no use of an arbitrary similarity measure** ($\boldsymbol{w_{ij}} \neq \boldsymbol{s_{ij}}$)
  - Explicitly account for interrelationships among the neighboring movies
- **Next: Latent factor model**
  - Extract "regional" correlations

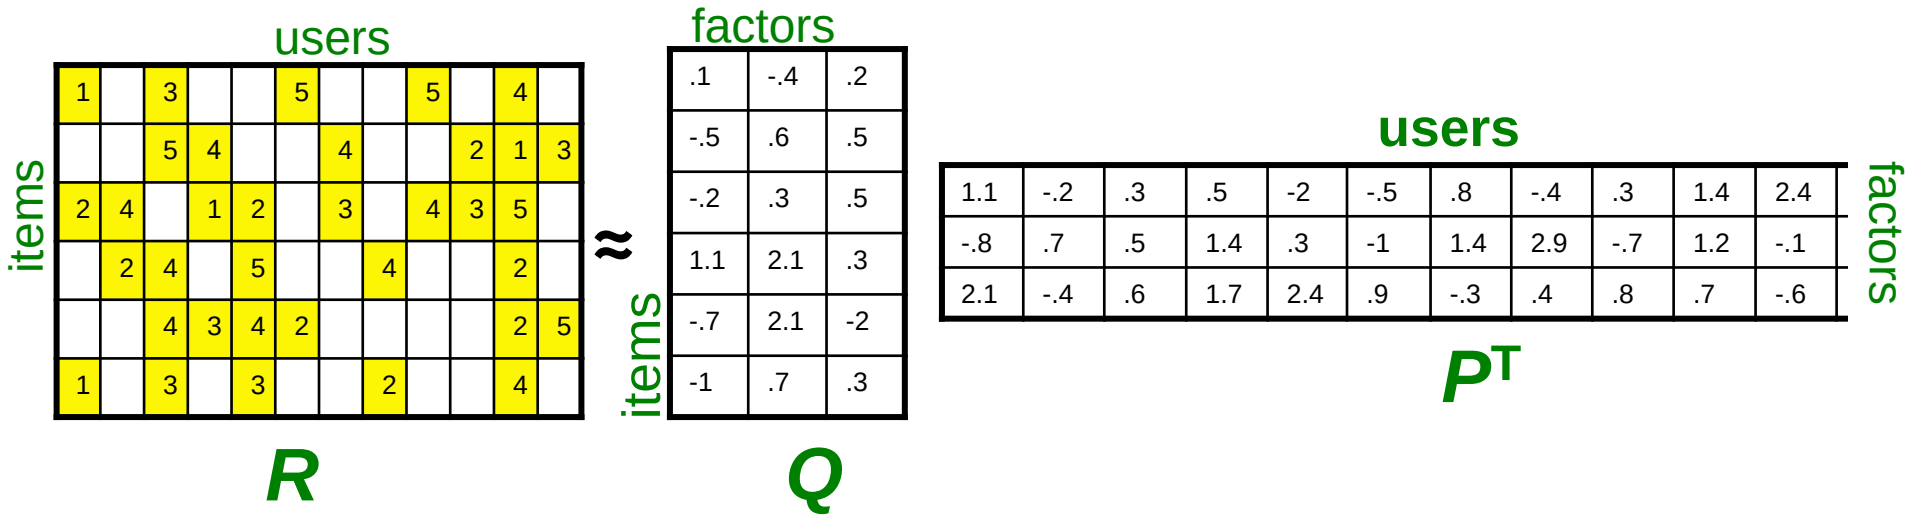


Performance of Various Methods



Latent Factor Models

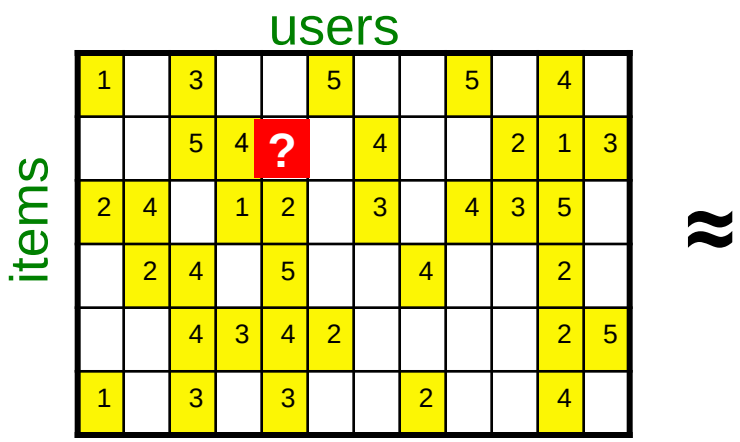
- Latent Factor Model on Netflix data: $\mathbf{R} \approx \boldsymbol{Q} \cdot \boldsymbol{P}^T$



- For now let's assume we can approximate the rating matrix $\boldsymbol{R}$ as a product of "thin" $\boldsymbol{Q} \cdot \boldsymbol{P}^T$
  - $\boldsymbol{R}$ has missing entries but let's ignore that for now!
    - Basically, we will want the reconstruction error to be small on known ratings and we don't care about the values on the missing ones

Ratings as Products of Factors

- **How to estimate the missing rating of user *x* for item *i*?**



≈

$$\hat{r}_{xi} = q_i \cdot p_x = \sum_f q_{if} \cdot p_{xf}$$

q_i = row i of Q
p_x = column x of P^T

.1	-.4	.2
-.5	.6	.5
-.2	.3	.5
1.1	2.1	.3
-.7	2.1	-2
-1	.7	.3

items × factors = Q

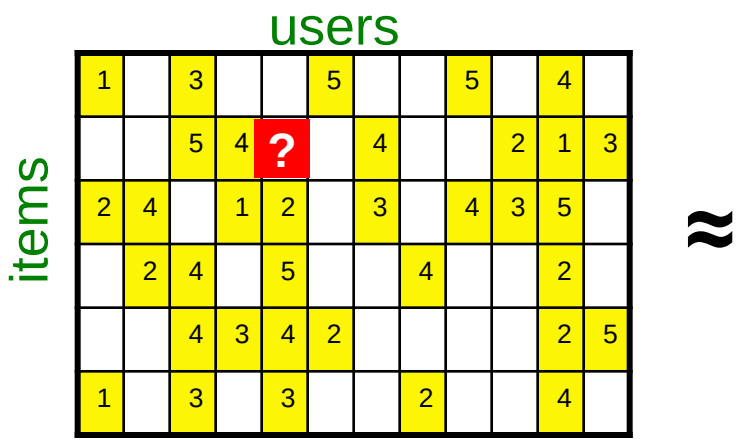
•

1.1	-.2	.3	.5	-2	-.5	.8	-.4	.3	1.4	2.4	-.9
-.8	.7	.5	1.4	.3	-1	1.4	2.9	-.7	1.2	-.1	1.3
2.1	-.4	.6	1.7	2.4	.9	-.3	.4	.8	.7	-.6	.1

factors × users = P^T

Ratings as Products of Factors

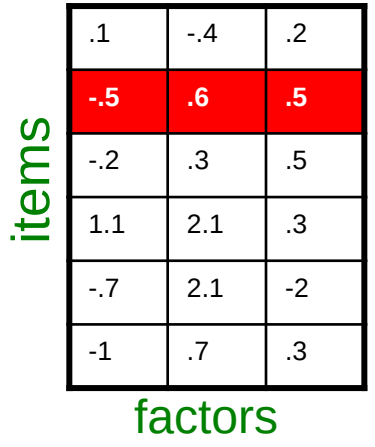
- **How to estimate the missing rating of user *x* for item *i*?**



≈

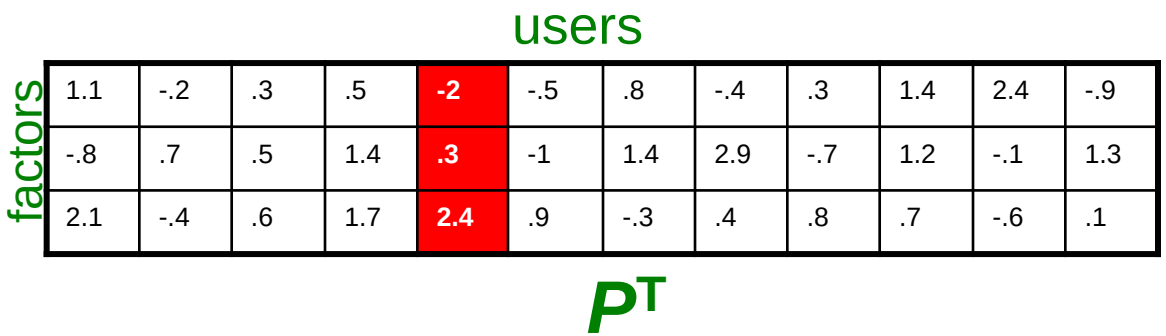
$$\hat{r}_{xi} = q_i \cdot p_x = \sum_f q_{if} \cdot p_{xf}$$

q_i = row i of Q
p_x = column x of P^T



Q

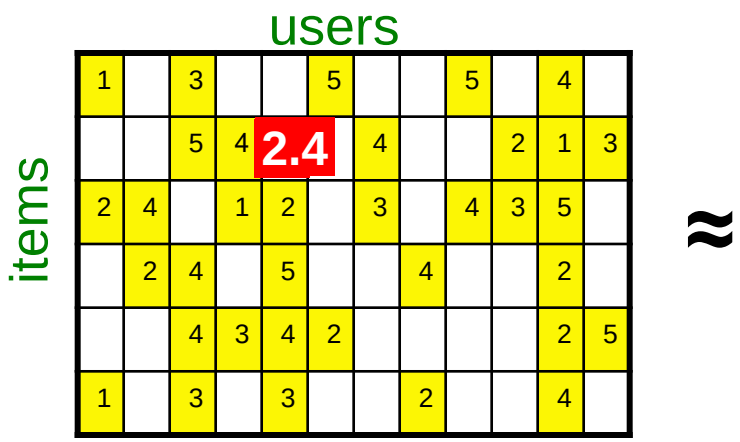
•



P^T

Ratings as Products of Factors

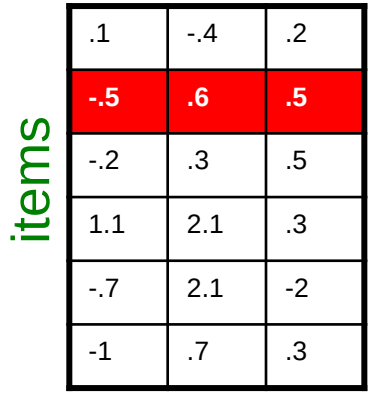
- **How to estimate the missing rating of user *x* for item *i*?**



≈

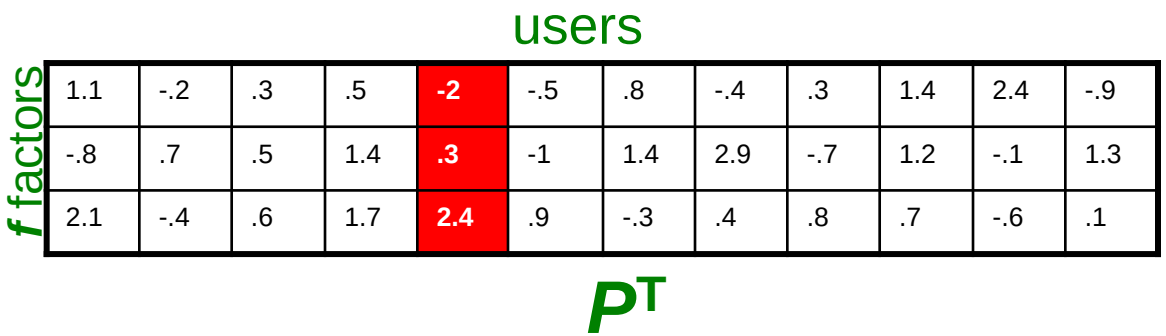
$$\hat{r}_{xi} = q_i \cdot p_x = \sum_f q_{if} \cdot p_{xf}$$

q_i = row i of Q
p_x = column x of P^T



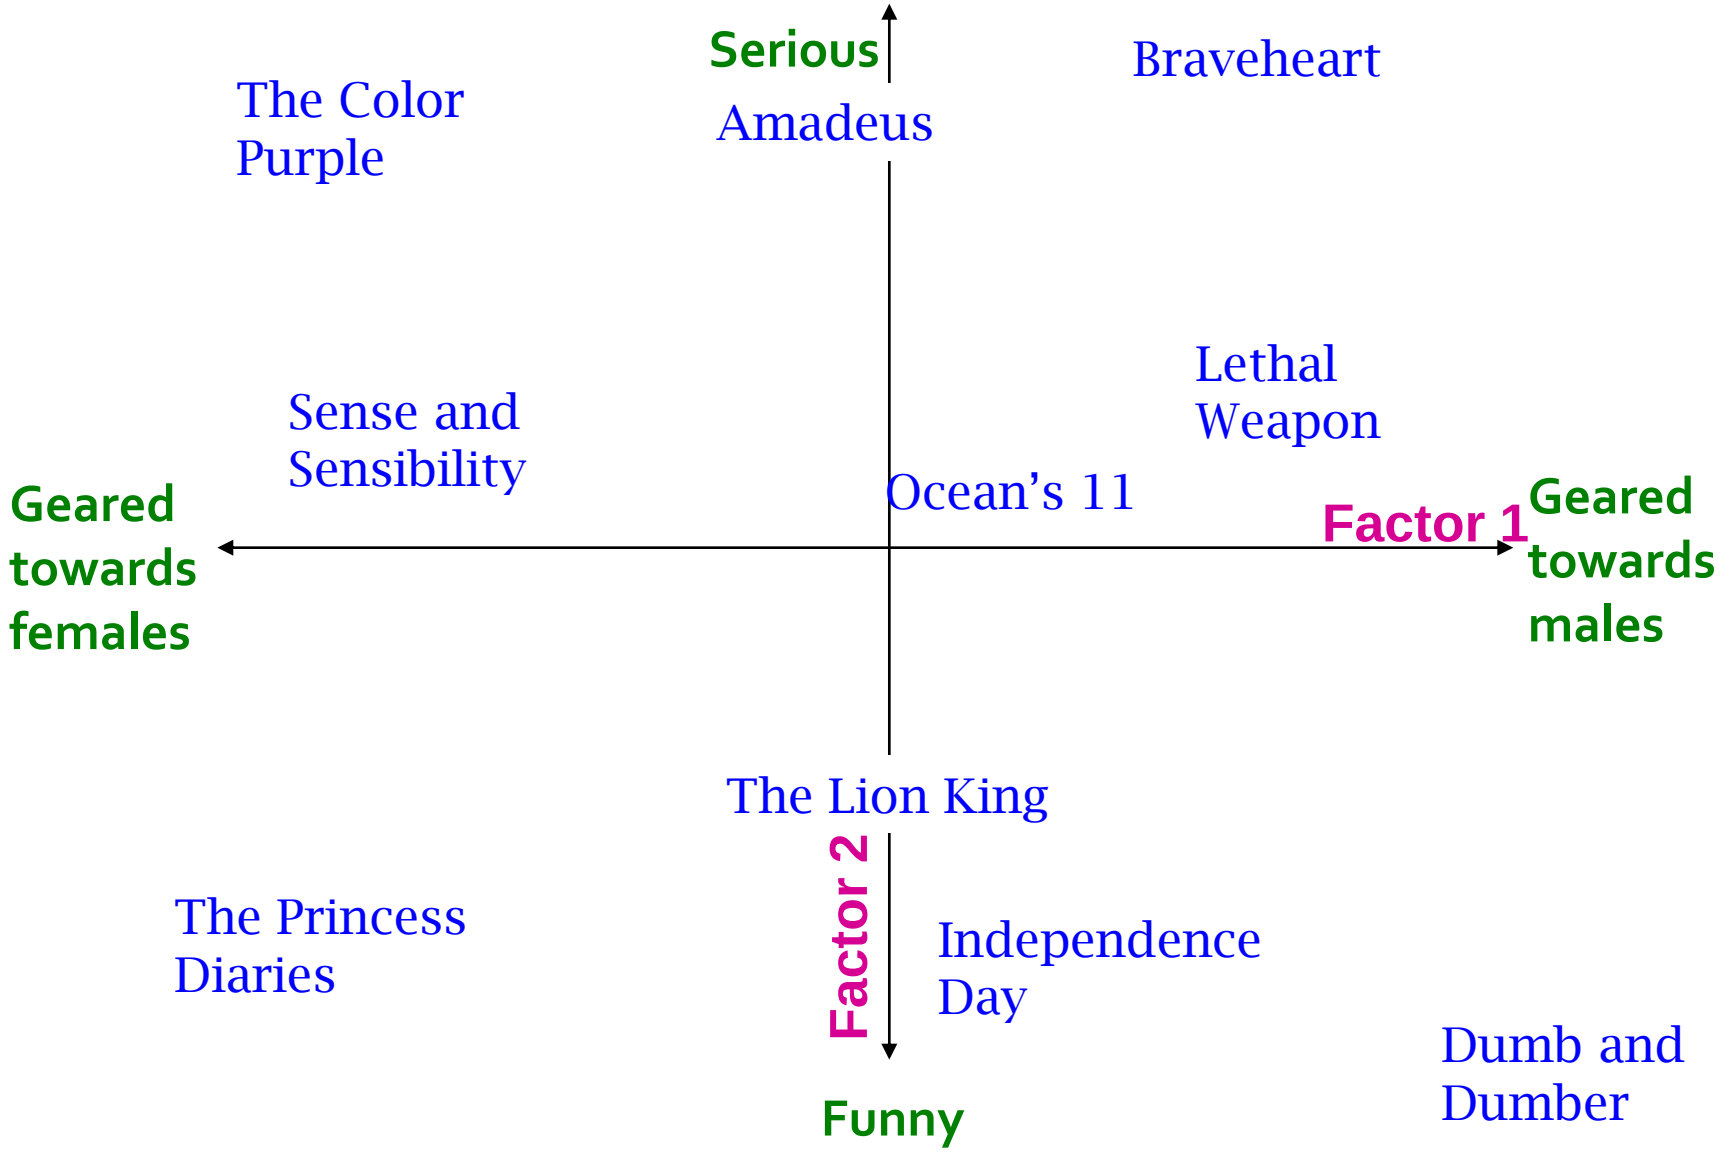
Q

•

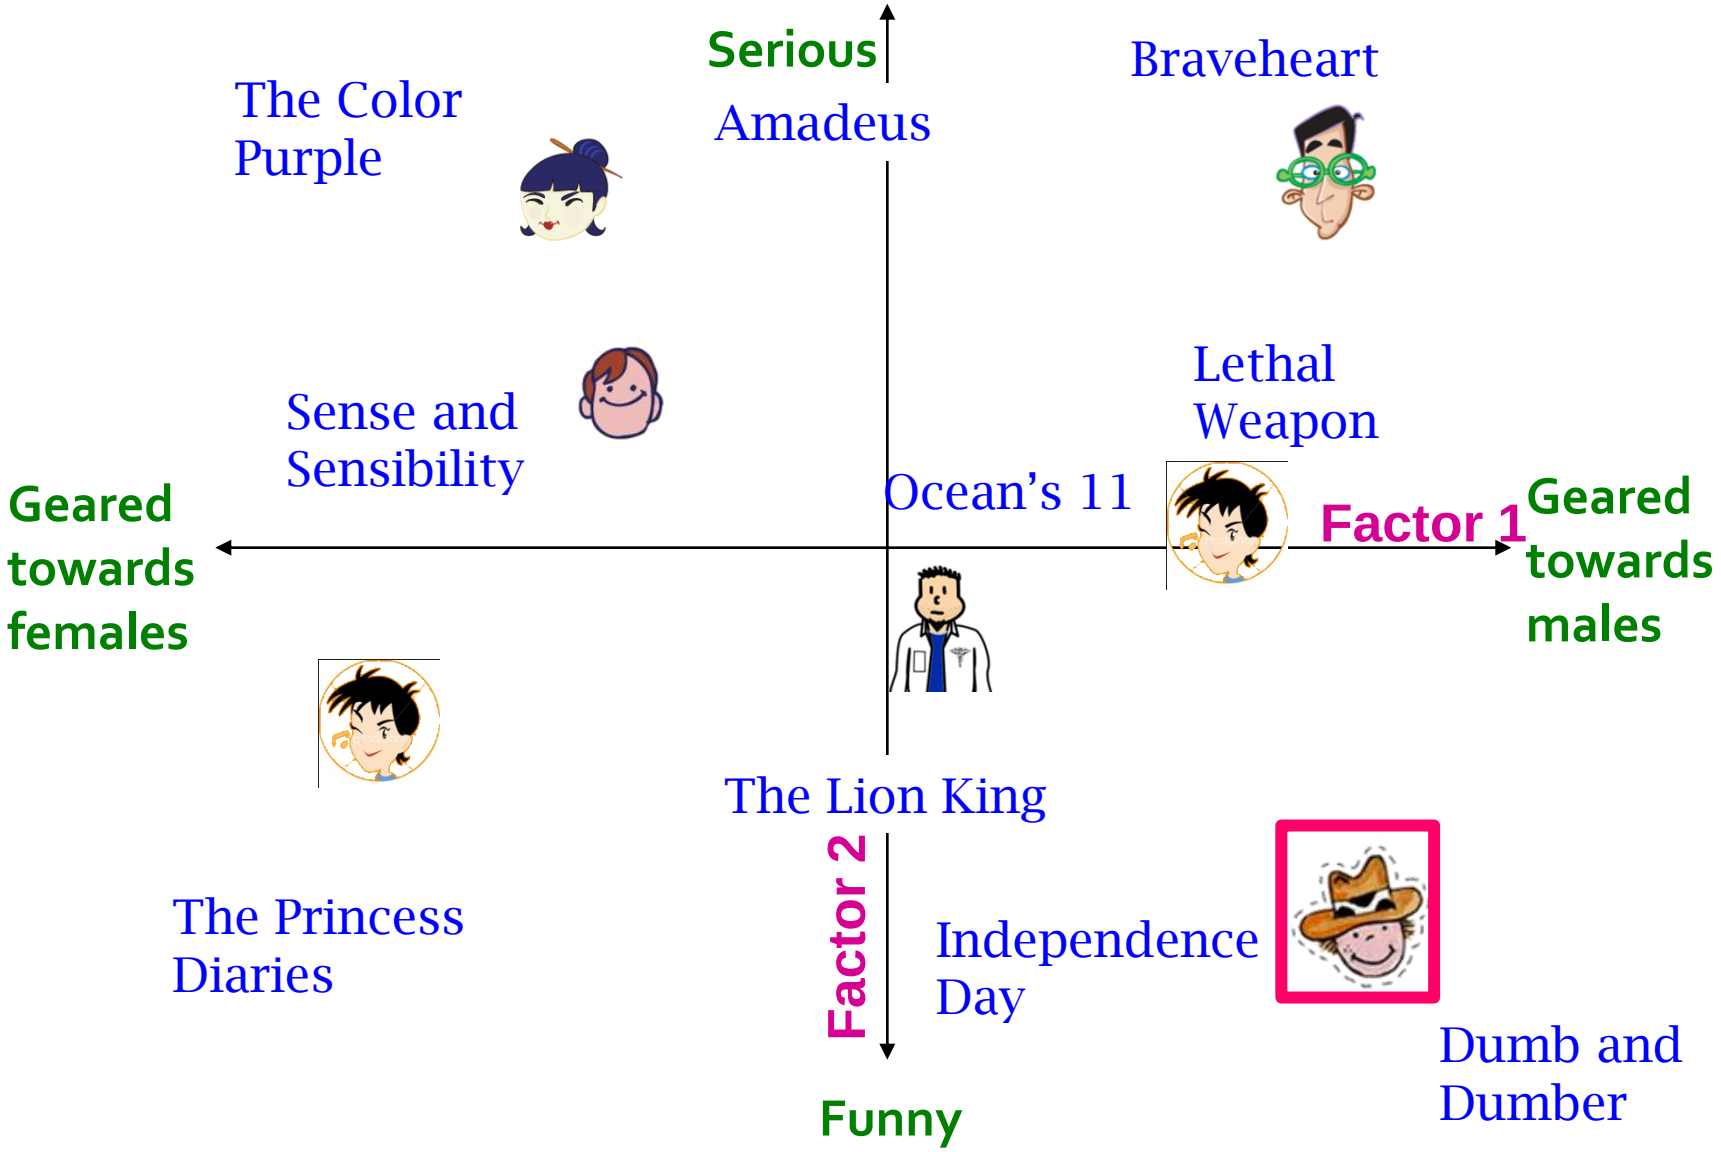


P^T

Latent Factor Models



Latent Factor Models

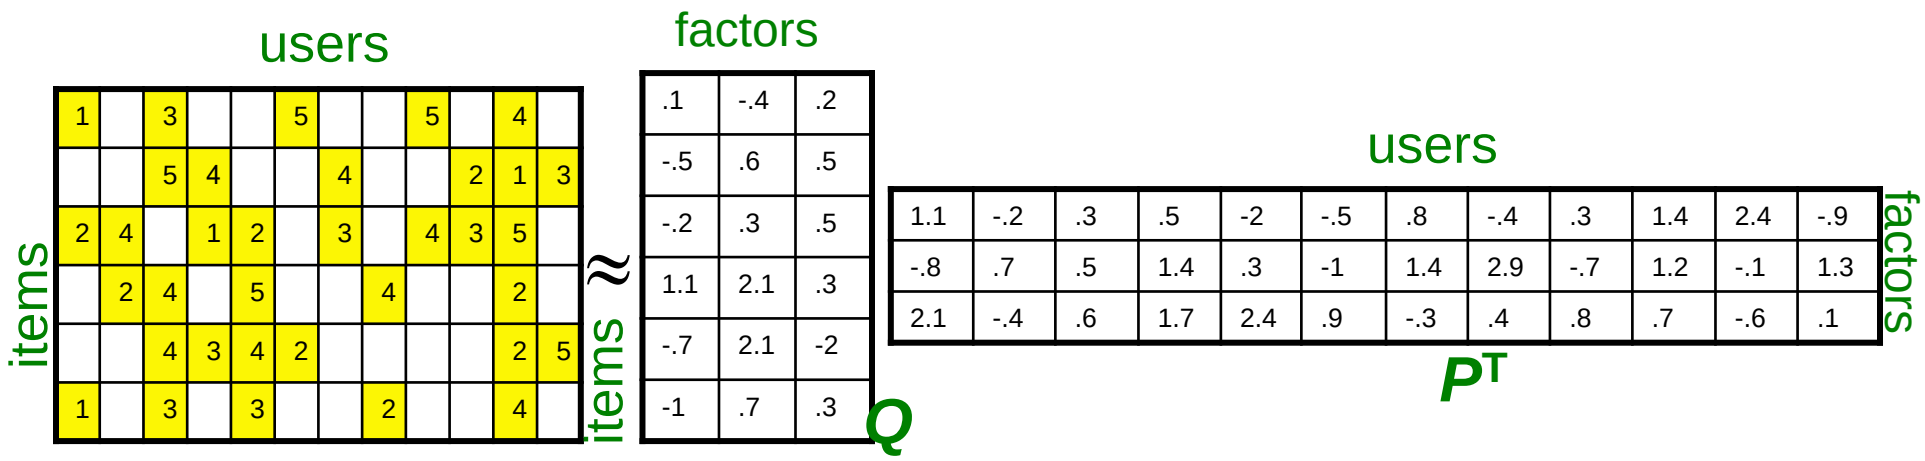


Finding the Latent Factors

Latent Factor Models

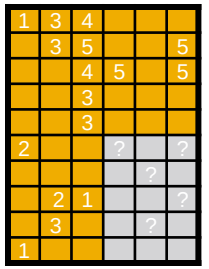
- **Our goal is to find P and Q such tat:**

$$\min_{P,Q} \sum_{(i,x)\in R} \left(r_{xi} - q_i \cdot p_x\right)^2$$



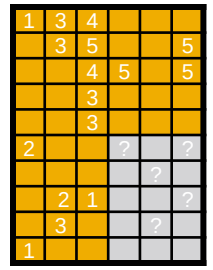
Back to Our Problem

- **Want to minimize sum of the squared errors (SSE) for unseen test data**
- **Idea: Minimize SSE on training data**
  - Want large ***k*** (# of factors) to capture all the signals
  - But, **SSE** on **test data** begins to rise for ***k*** > 2



- This is a classical example of **overfitting:**
  - With too much freedom (too many free parameters) the model starts fitting noise
    - That is it fits too well the training data and thus **not generalizing** well to unseen test data

Dealing with Missing Entries

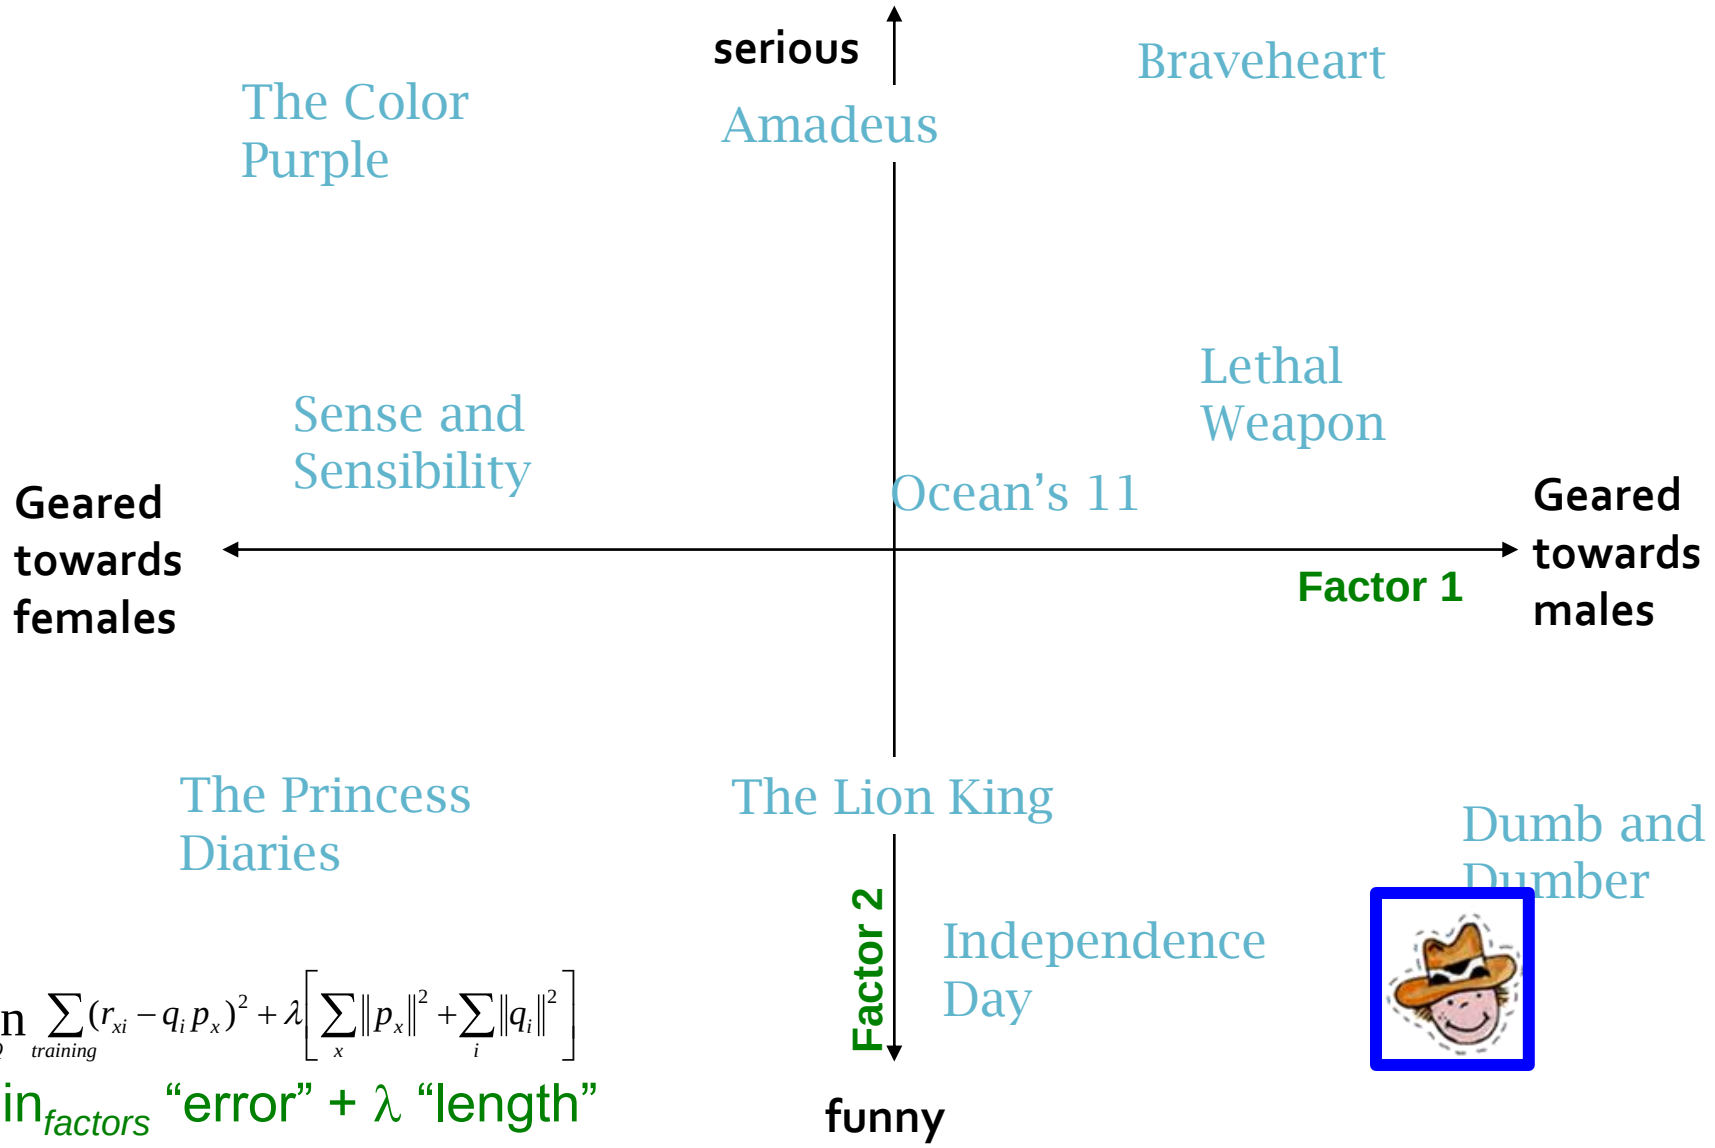


- **To solve overfitting we introduce regularization:**
  - Allow rich model where there is sufficient data
  - Shrink aggressively where data is scarce

$$\min_{P,Q} \underbrace{\sum_{training} (r_{xi} - q_i p_x)^2}_{\text{“error”}} + \underbrace{\left[\lambda_1 \sum_x \|p_x\|^2 + \lambda_2 \sum_i \|q_i\|^2 \right]}_{\text{“length”}}$$

λ_1, λ_2 … user set regularization parameters

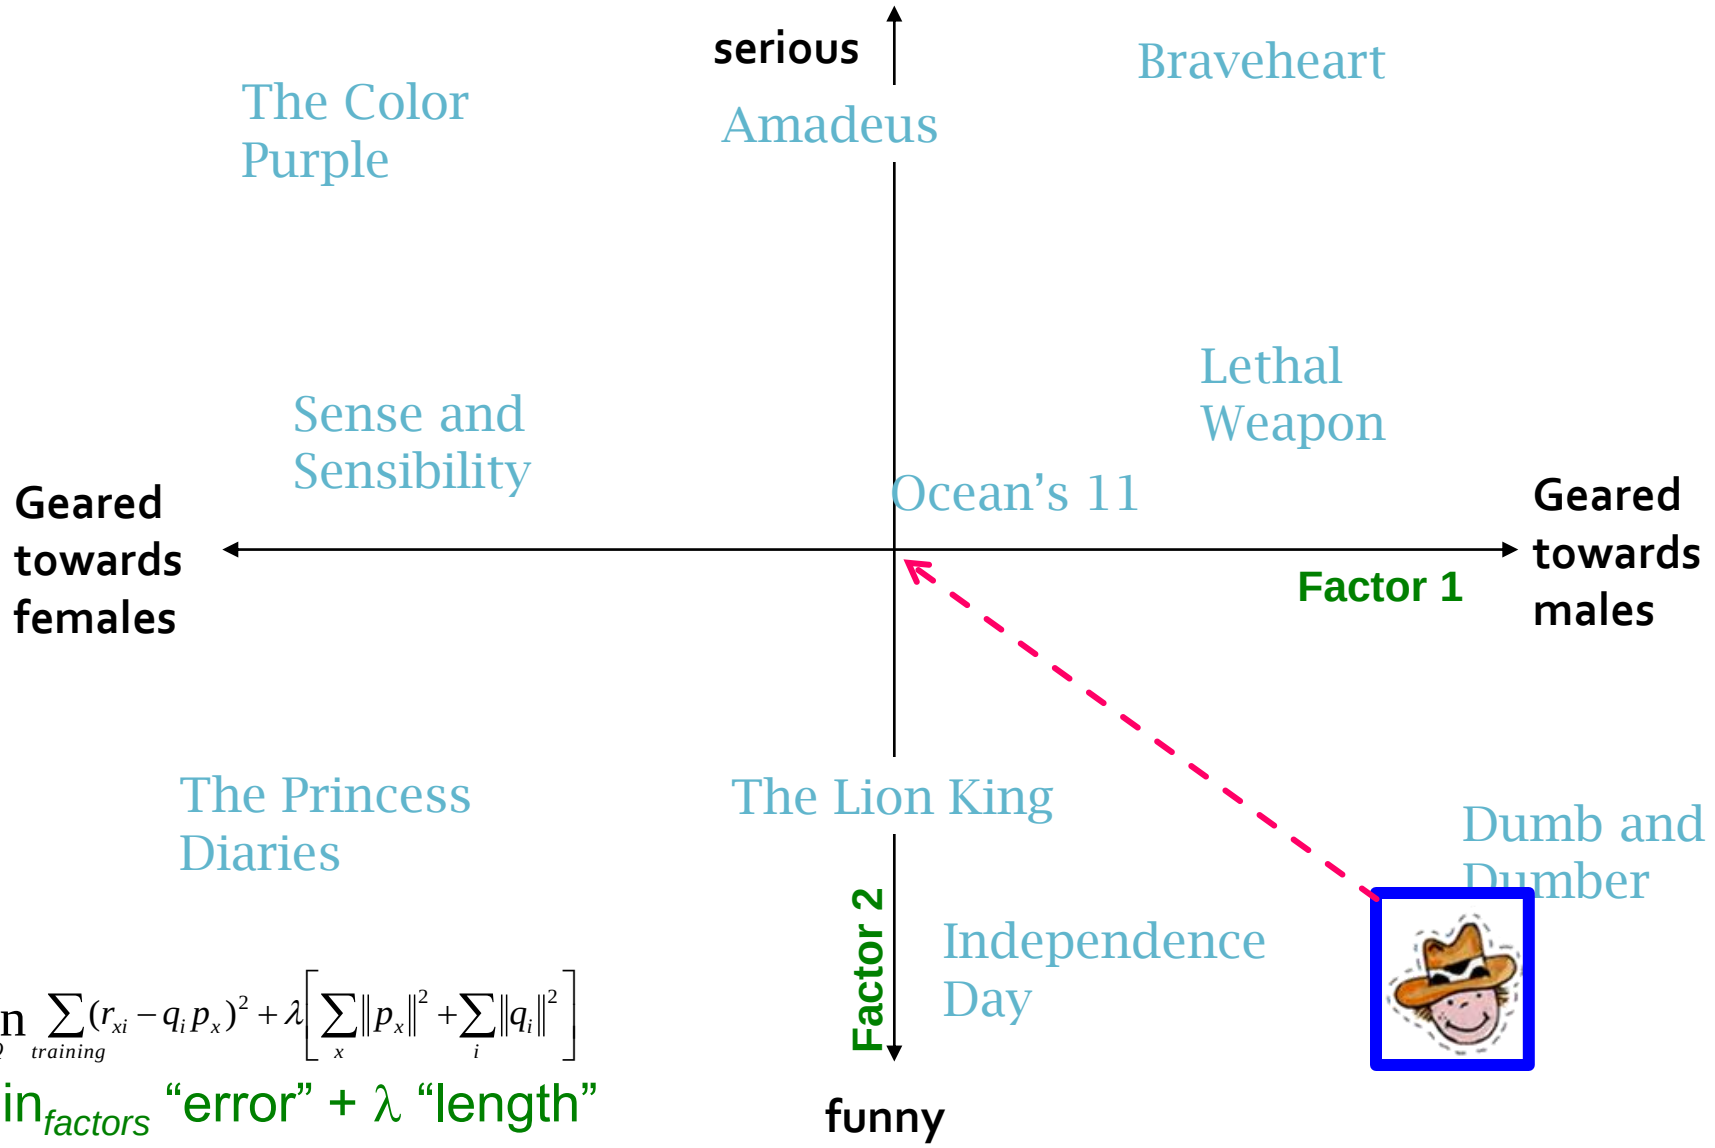
The Effect of Regularization



$$\min_{P,Q} \sum_{training} (r_{xi} - q_i p_x)^2 + \lambda \left[\sum_x \|p_x\|^2 + \sum_i \|q_i\|^2 \right]$$

$\min_{factors}$ "error" + λ "length"

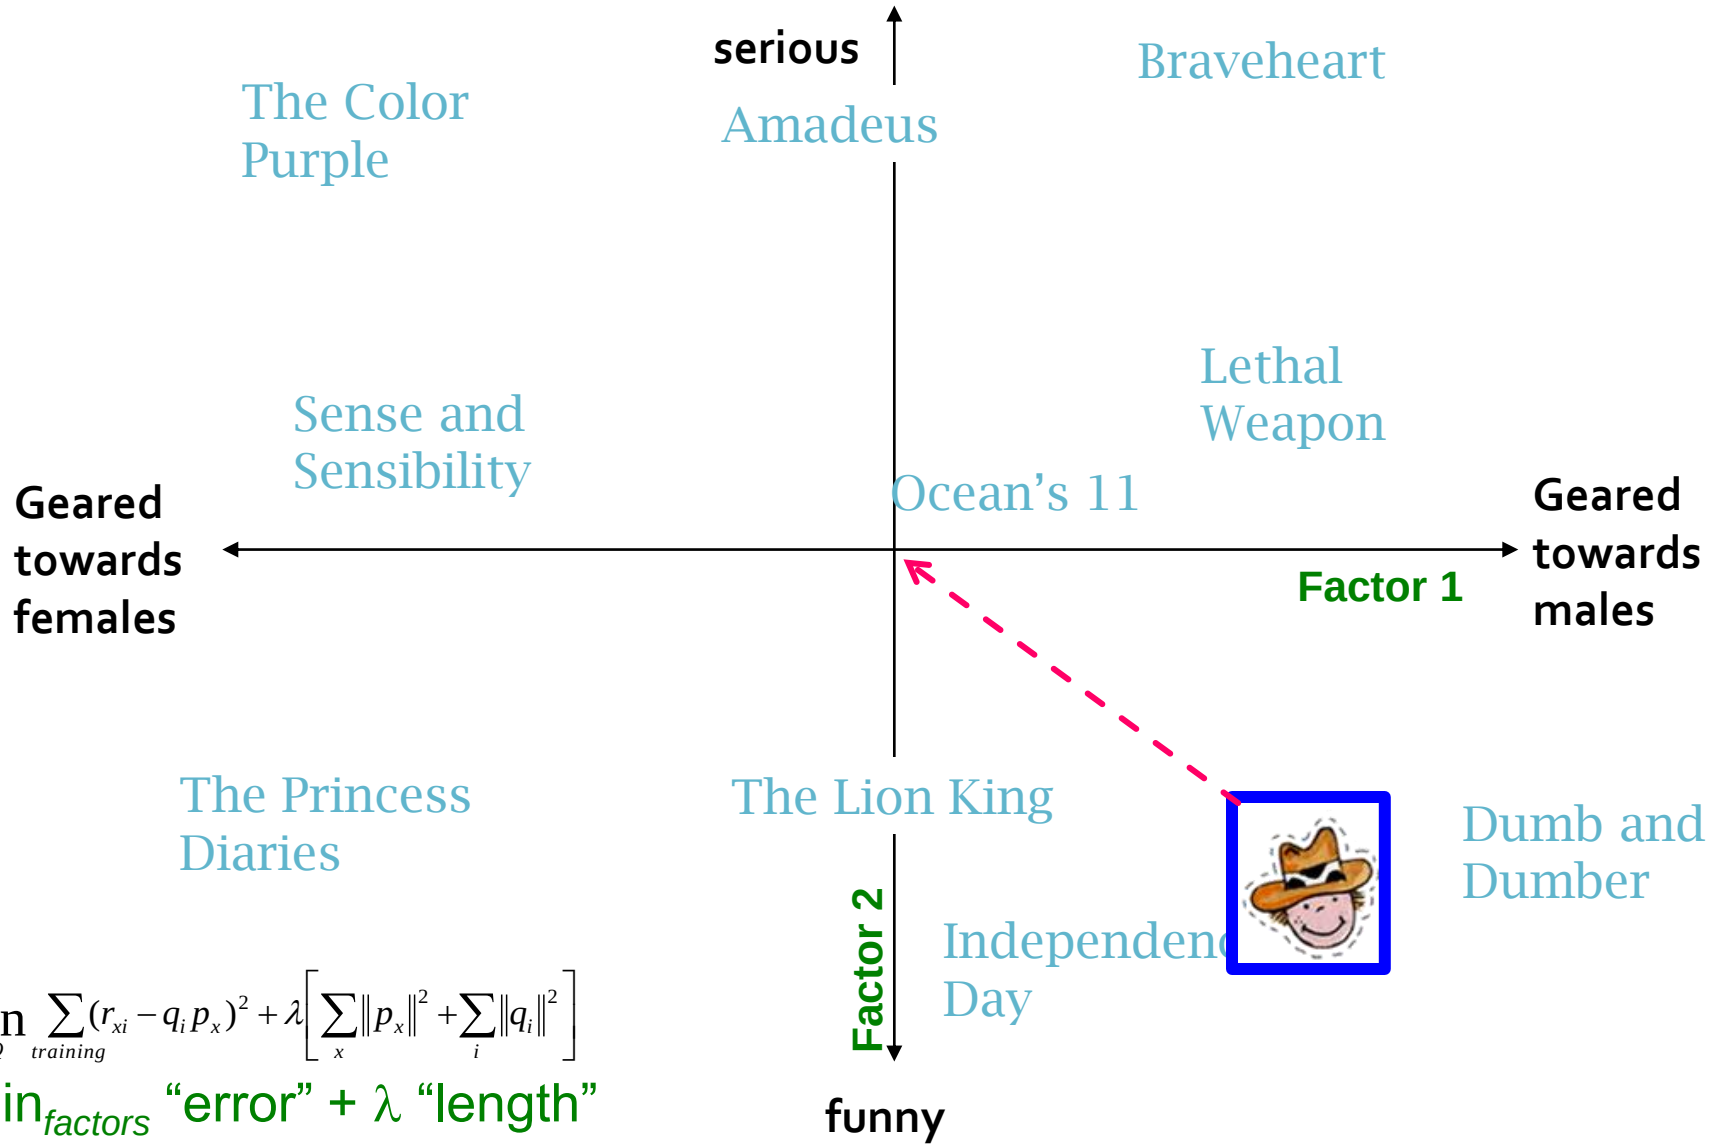
The Effect of Regularization



$$\min_{P,Q} \sum_{training} (r_{xi} - q_i p_x)^2 + \lambda \left[\sum_x \|p_x\|^2 + \sum_i \|q_i\|^2 \right]$$

$\min_{factors}$ "error" + λ "length"

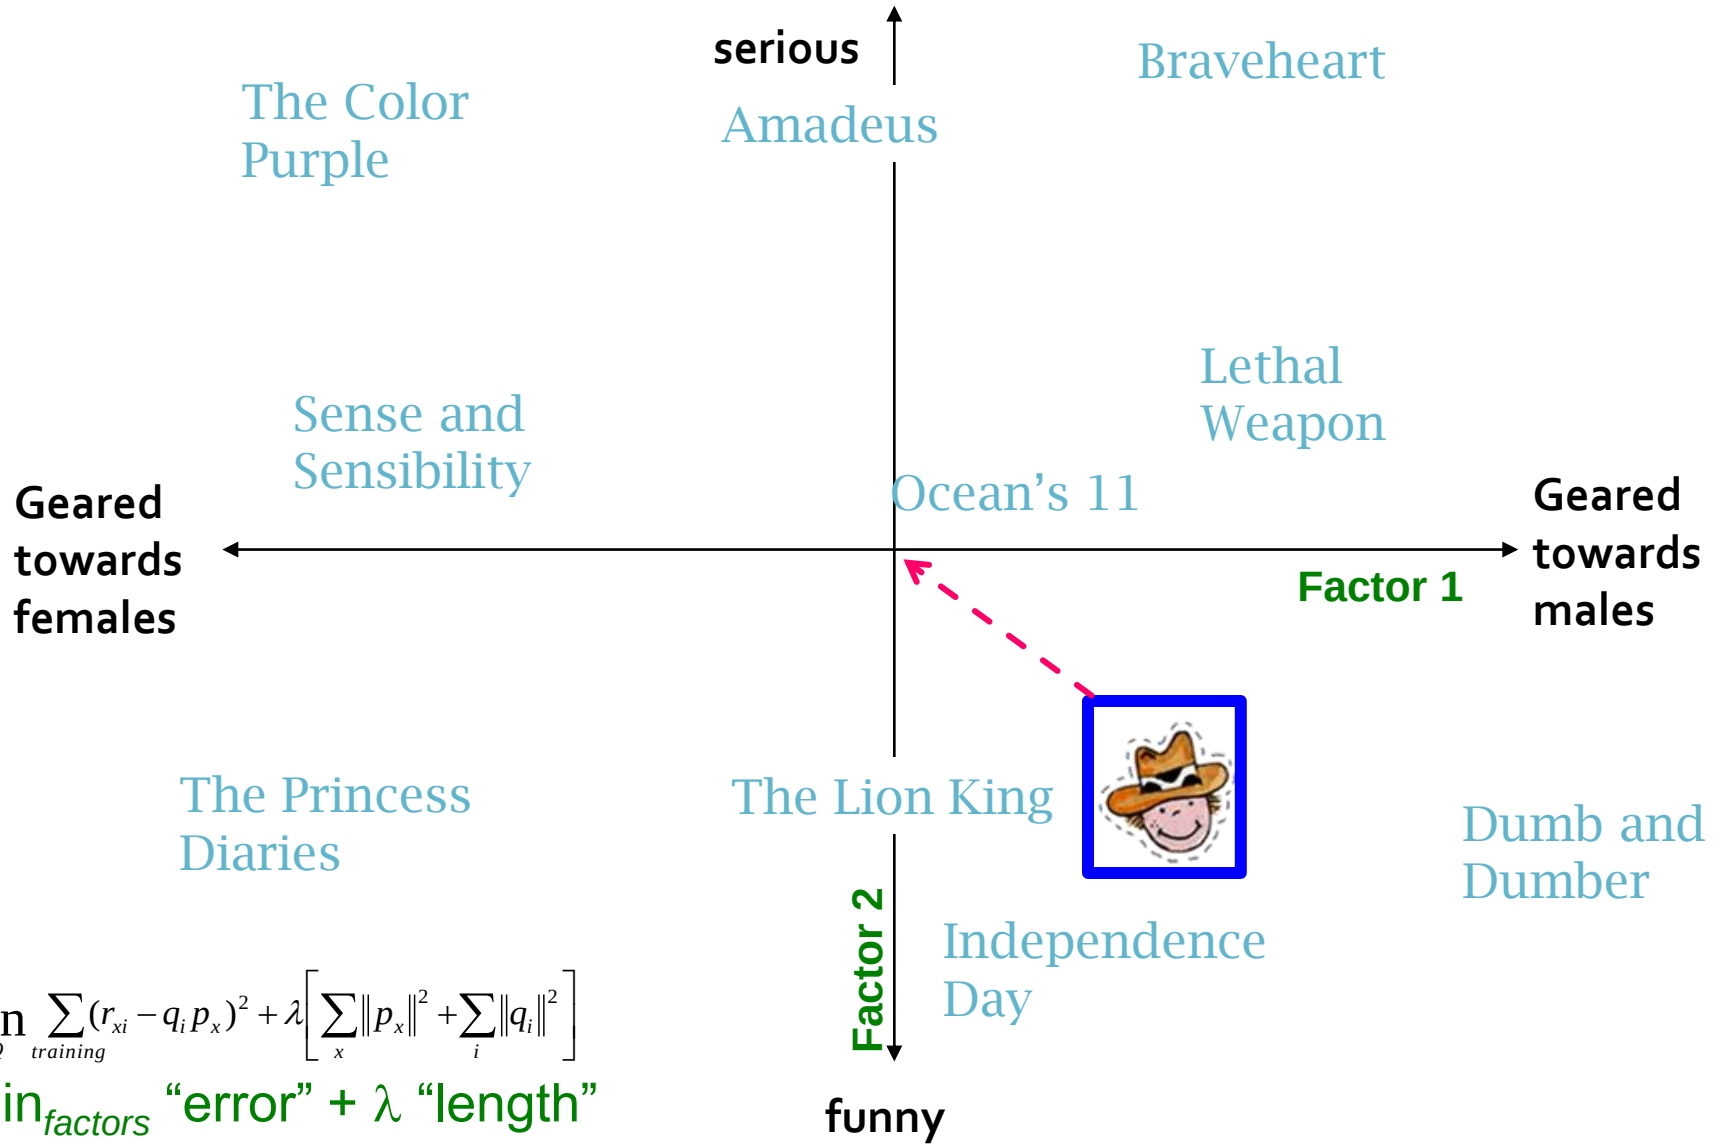
The Effect of Regularization



$$\min_{P,Q} \sum_{training} (r_{xi} - q_i p_x)^2 + \lambda \left[\sum_x \|p_x\|^2 + \sum_i \|q_i\|^2 \right]$$

$\min_{factors}$ "error" + λ "length"

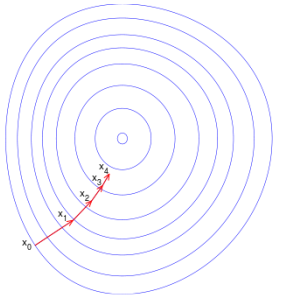
The Effect of Regularization



$$\min_{P,Q} \sum_{training} (r_{xi} - q_i p_x)^2 + \lambda \left[\sum_x \|p_x\|^2 + \sum_i \|q_i\|^2 \right]$$

$\min_{factors}$ "error" + λ "length"

Stochastic Gradient Descent



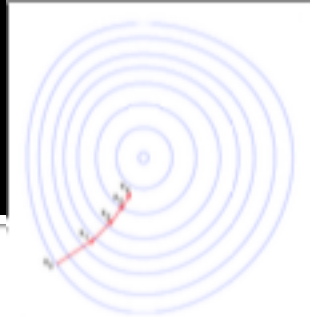
- **Want to find matrices *P* and *Q*:**

$$\min_{P,Q} \sum_{training} (r_{xi} - q_i p_x)^2 + \left[\lambda_1 \sum_x \|p_x\|^2 + \lambda_2 \sum_i \|q_i\|^2 \right]$$

- **Gradient descent:**
  - Initialize ***P*** and ***Q*** (using SVD, pretend missing ratings are 0)
  - Do gradient descent:
    - $P \leftarrow P - \eta \cdot \nabla P$
    - $Q \leftarrow Q - \eta \cdot \nabla Q$
    - where ∇Q is gradient/derivative of matrix ***Q***:
      $\nabla Q = [\nabla q_{if}]$ and $\nabla q_{if} = \sum_{x,i} -2(r_{xi} - q_i p_x) p_{xf} + 2\lambda_2 q_{if}$
      - Here q_{if} is entry ***f*** of row q_i of matrix ***Q***
  - **Observation: Computing gradients is slow!**

How to compute gradient of a matrix?
Compute gradient of every element independently!

Stochastic Gradient Descent



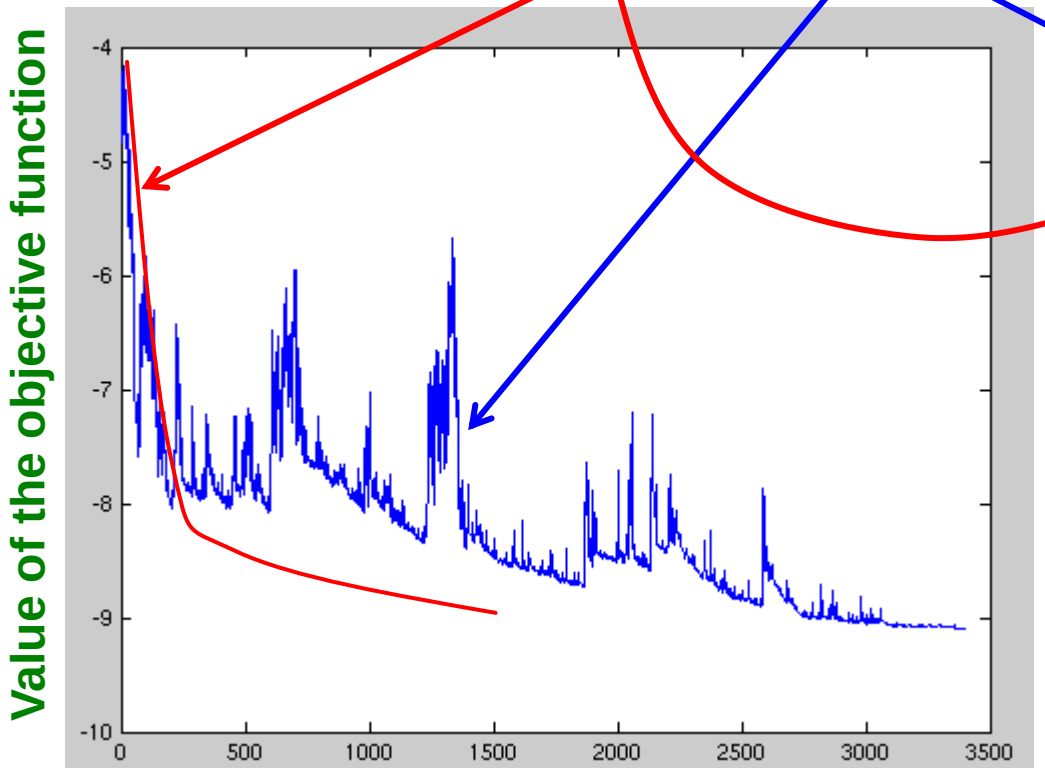
- **Gradient Descent (GD) vs. Stochastic GD**
  - **Observation:** $\nabla Q = [\nabla q_{if}]$ where

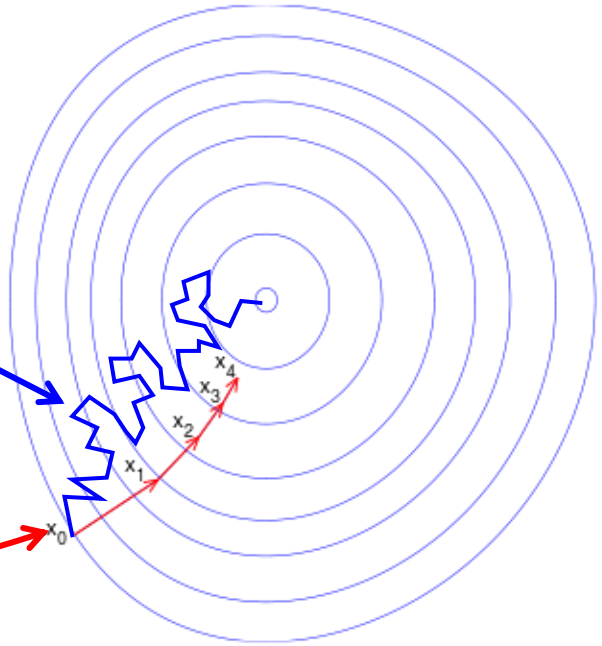
$$\nabla q_{if} = \sum_{x,i} -2\left(r_{xi} - q_{if}p_{xf}\right)p_{xf} + 2\lambda q_{if} = \sum_{x,i} \nabla \boldsymbol{Q}\left(\boldsymbol{r_{xi}}\right)$$

    - Here $\boldsymbol{q_{if}}$ is entry $\boldsymbol{f}$ of row $\boldsymbol{q_i}$ of matrix $\boldsymbol{Q}$
  - $\boldsymbol{Q} = \boldsymbol{Q} - \eta\nabla\boldsymbol{Q} = \boldsymbol{Q} - \eta\left[\sum_{x,i} \nabla \boldsymbol{Q}\left(\boldsymbol{r_{xi}}\right)\right]$
  - **Idea:** Instead of evaluating gradient over all ratings evaluate it for each individual rating and make a step
- **GD:** $\boldsymbol{Q} \leftarrow \boldsymbol{Q} - \eta\left[\sum_{\boldsymbol{r_{xi}}} \nabla \boldsymbol{Q}\left(\boldsymbol{r_{xi}}\right)\right]$
- **SGD:** $\boldsymbol{Q} \leftarrow \boldsymbol{Q} - \mu\nabla \boldsymbol{Q}\left(\boldsymbol{r_{xi}}\right)$
  - **Faster convergence!**
    - Need more steps but each step is computed much faster

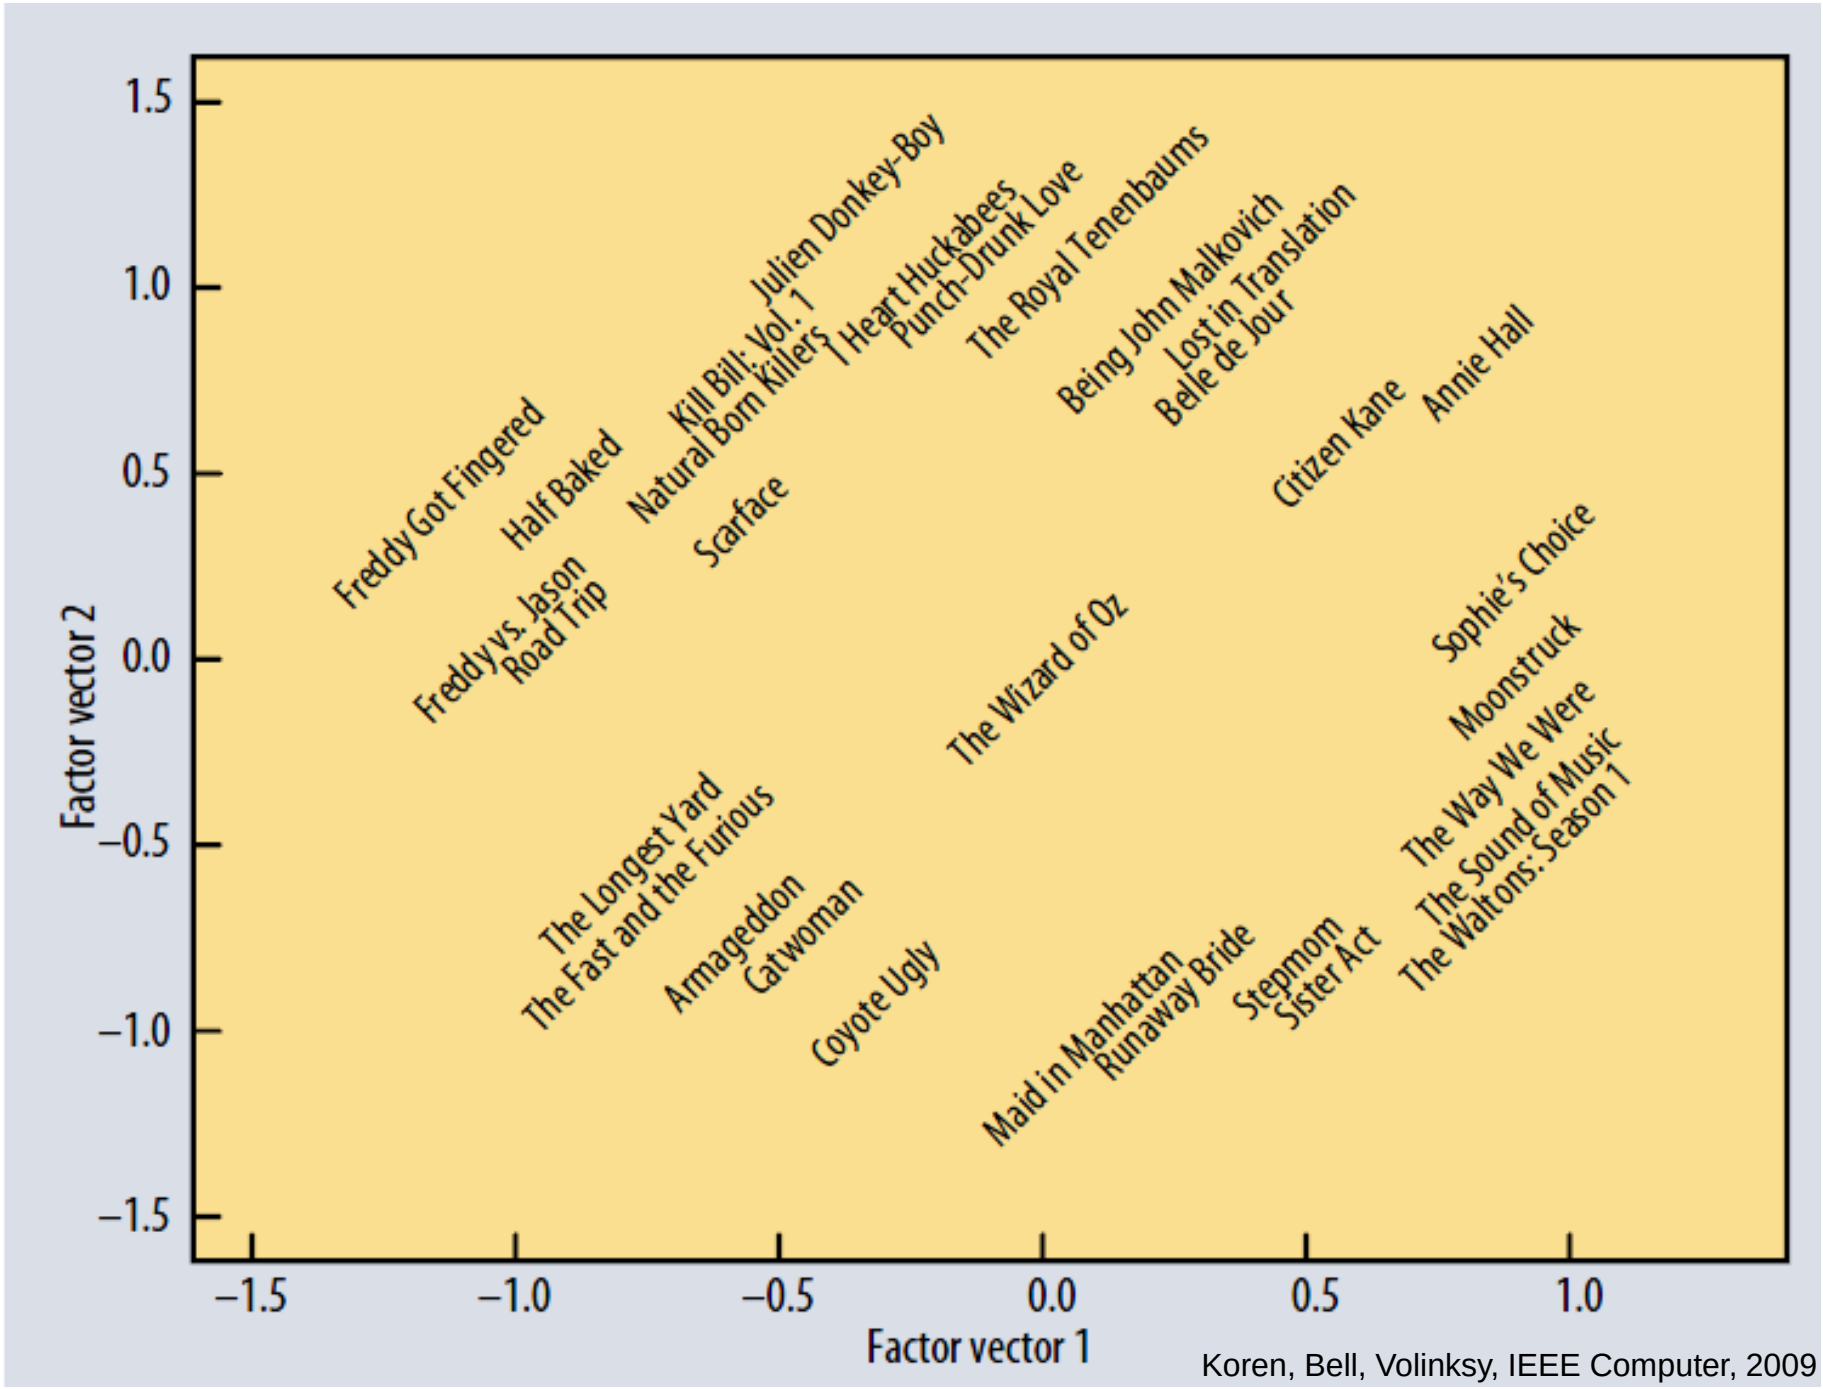
SGD vs. GD

- **Convergence of GD vs. SGD**





GD improves the value of the objective function at every step.
SGD improves the value but in a "noisy" way.
GD takes fewer steps to converge but each step takes much longer to compute.
In practice, **SGD** is much faster!



Koren, Bell, Volinksy, IEEE Computer, 2009

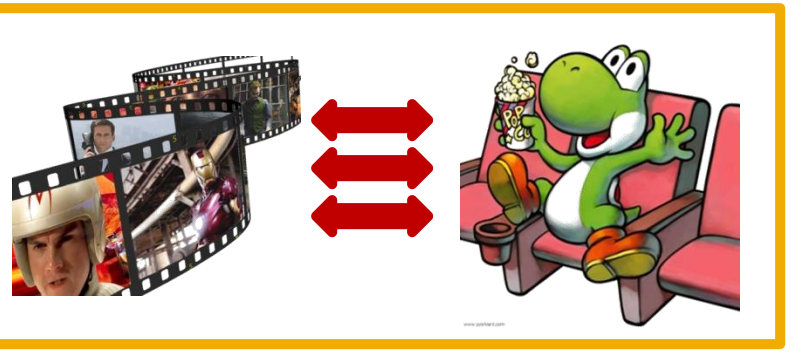
Extending Latent Factor Model to Include Biases

Modeling Biases and Interactions

user bias

movie bias

user-movie interaction



Baseline predictor

- Separates users and movies
- Benefits from insights into user's behavior
- Among the main practical contributions of the competition

User-Movie interaction

- Characterizes the matching between users and movies
- Attracts most research in the field
- Benefits from algorithmic and mathematical innovations

- μ = overall mean rating
- b_x = bias of user x
- b_i = bias of movie i

Putting It All Together

$$r_{xi} = \mu + b_x + b_i + q_i \cdot p_x$$

- μ: Overall mean rating
- b_x: Bias for user ***x***
- b_i: Bias for movie ***i***
- $q_i \cdot p_x$: User-Movie interaction

- **Example:**
  - Mean rating: $\mu = 3.7$
  - You are a critical reviewer: your ratings are 1 star lower than the mean: $b_x = -1$
  - Star Wars gets a mean rating of *0.5* higher than average movie: $b_i = +0.5$
  - Predicted rating for you on Star Wars:
    $= 3.7 - 1 + 0.5 = 3.2$

Fitting the New Model

- **Solve:**

$$\min_{Q,P} \sum_{(x,i)\in R} \left(r_{xi} - (\mu + b_x + b_i + q_i\, p_x)\right)^2$$

goodness of fit

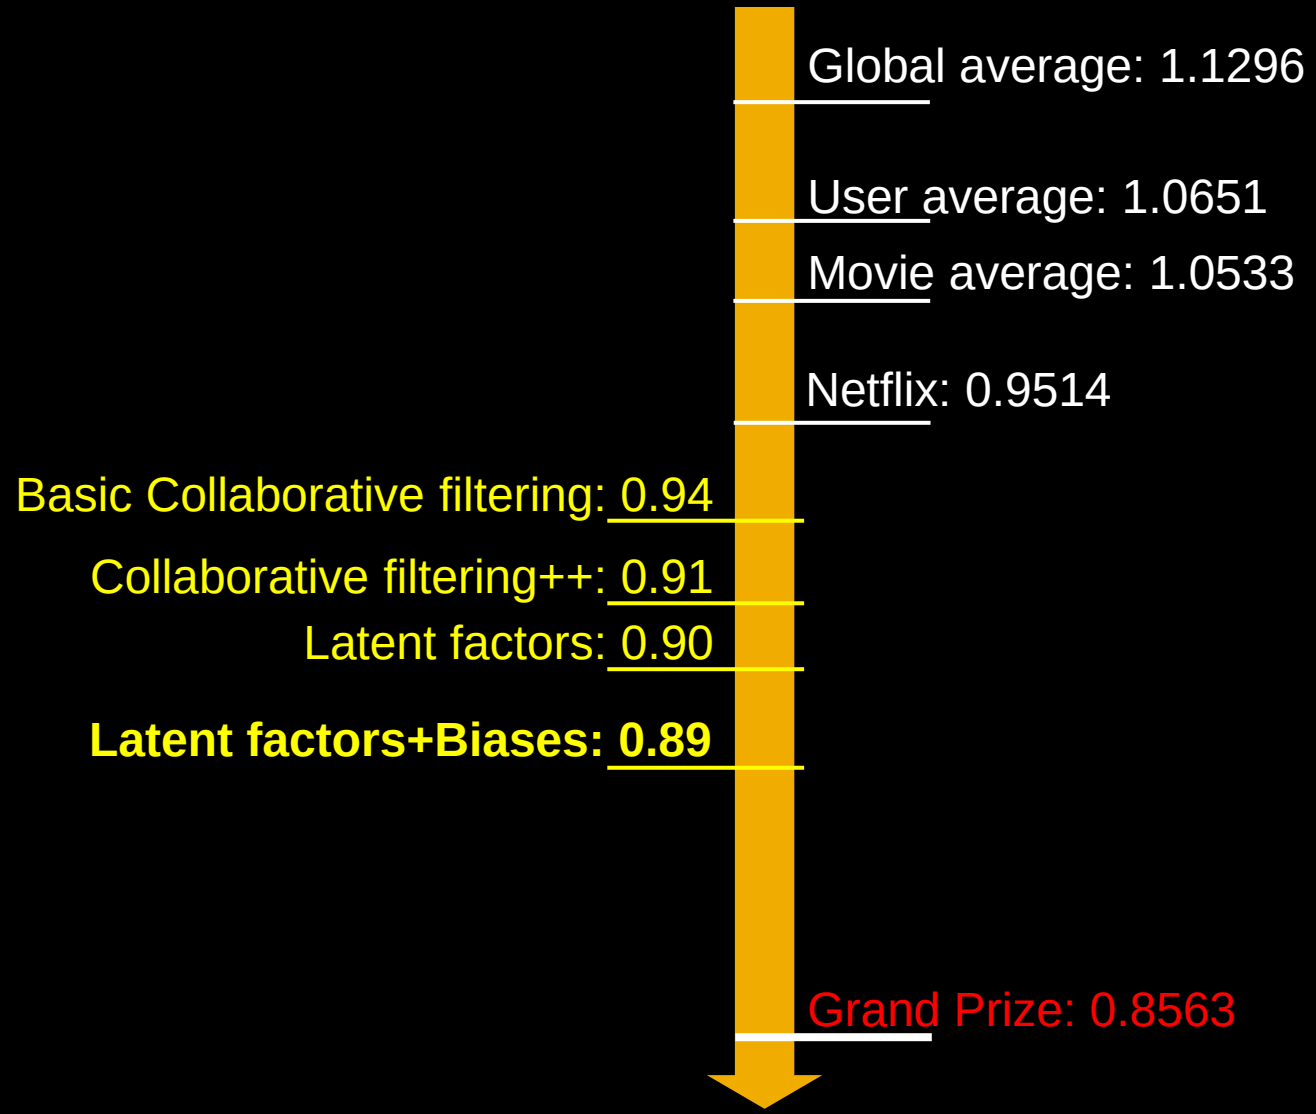
$$+\left(\lambda_1 \sum_i \|q_i\|^2 + \lambda_2 \sum_x \|p_x\|^2 + \lambda_3 \sum_x \|b_x\|^2 + \lambda_4 \sum_i \|b_i\|^2\right)$$

regularization

λ is selected via grid-search on a validation set

- **Stochastic gradient decent to find parameters**
  - **Note:** Both biases b_x, b_i as well as interactions q_i, p_x are treated as parameters (and we learn them)

Performance of Various Methods

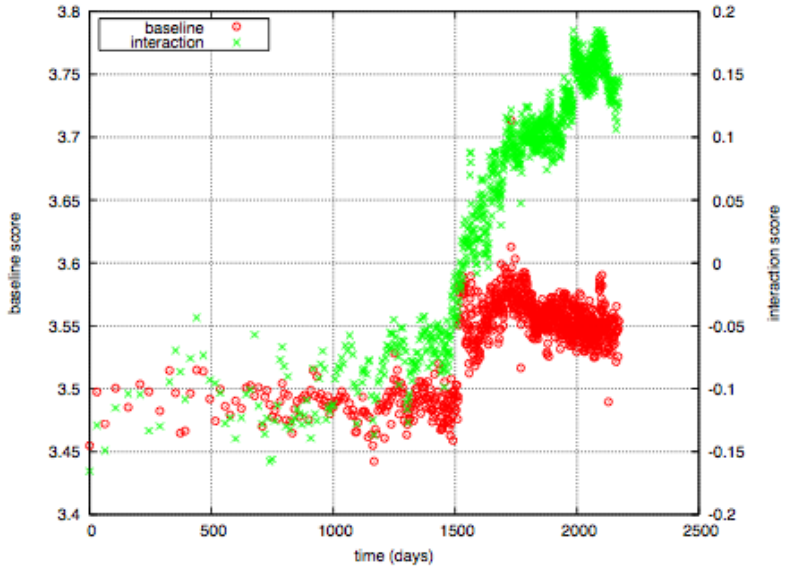


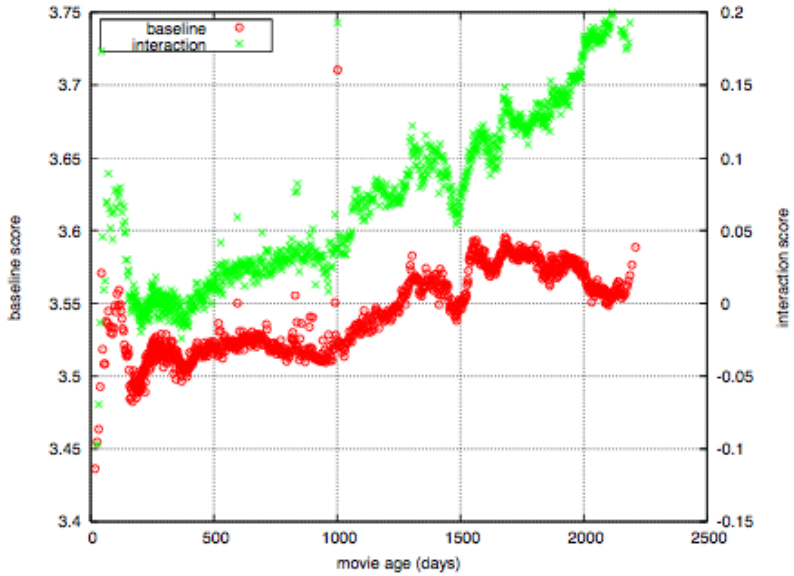
The Netflix Challenge: 2006-09

Temporal Biases Of Users

- **Sudden rise in the average movie rating** (early 2004)
  - Improvements in Netflix
  - GUI improvements
  - Meaning of rating changed
- **Movie age**
  - Users prefer new movies without any reasons
  - Older movies are just inherently better than newer ones

Y. Koren, Collaborative filtering with temporal dynamics, KDD '09





Temporal Biases & Factors

- **Original model:**

  $r_{xi} = \mu + b_x + b_i + q_i \cdot p_x$

- **Add time dependence to biases:**

  $r_{xi} = \mu + b_x(t) + b_i(t) + q_i \cdot p_x$

  - Make parameters b_x and b_i to depend on time
  - **(1)** Parameterize time-dependence by linear trends
    (2) Each bin corresponds to 10 consecutive weeks

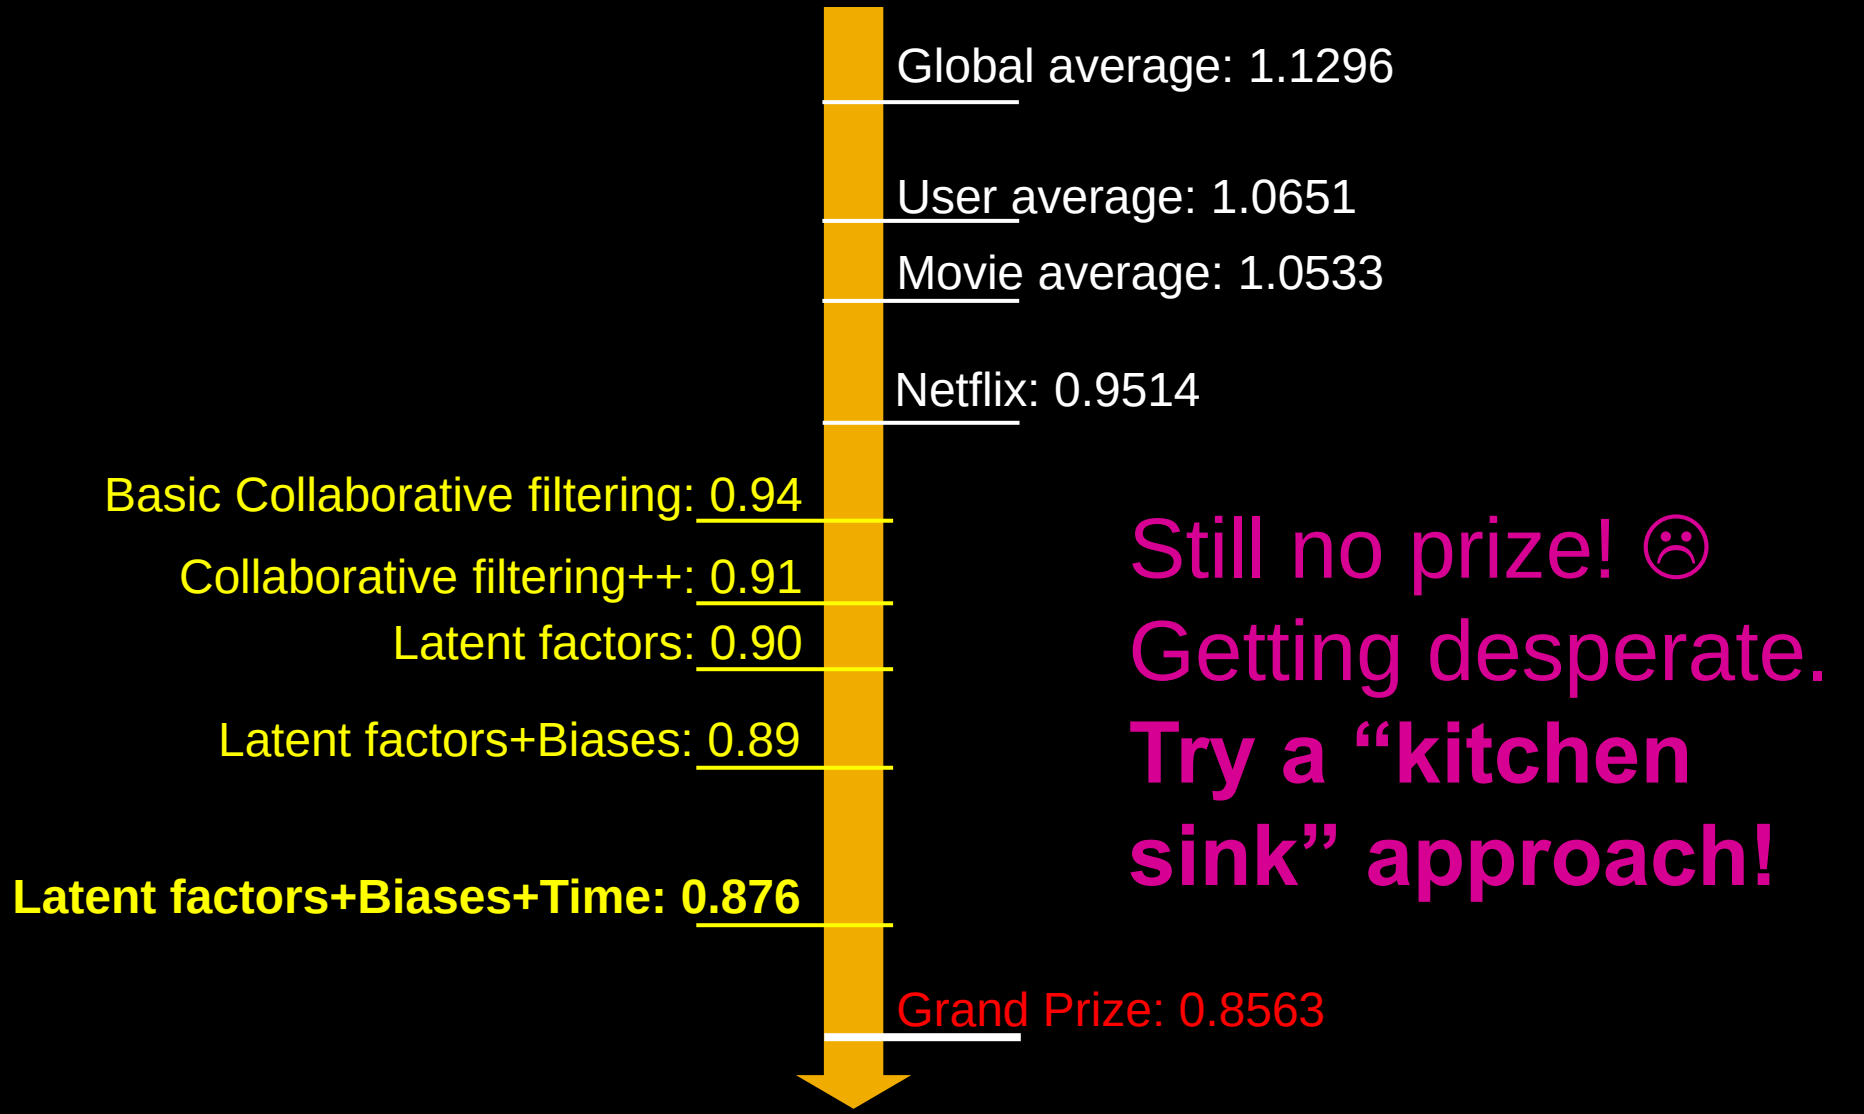
    $$b_i(t) = b_i + b_{i,\mathrm{Bin}(t)}$$

- **Add temporal dependence to factors**

  - $p_x(t)$… user preference vector on day t

Y. Koren, Collaborative filtering with temporal dynamics, KDD '09

Performance of Various Methods



Still no prize! ☹
Getting desperate.
Try a "kitchen sink" approach!

The big picture
